THE SENSITIVITY OF BUCKLING OF AXIALLY COMPRESSED FIBER-REINFORCED CYLINDRICAL SHELLS TO SMALL GEOMETRIC IMPERFECTIONS

by

Michael F. Card

ABSTRACT

An index of imperfection sensitivity is obtained by investigating the character of the initial postbuckling region for a geometrically perfect cylindrical shell. Using techniques of perturbation theory, equations governing postbuckling behavior of a multilayered, orthotropic cylinder are developed. The theory considers the effects of nonlinear deformations induced by loading prior to buckling. Solutions for postbuckling displacements are obtained by converting the governing equations and boundary conditions to a system of second-order differential equations, which are then written in terms of finite differences at stations along the length of the cylinder. The resulting algebraic equations are solved by matrix algebra exploiting Gaussian elimination. A computer program was developed to solve the resulting large systems of simultaneous equations and to perform the numerical differentiation and integration necessary to calculate the imperfection sensitivity index.

Relative values of the imperfection sensitivity index are investigated for three types of fiber-reinforced cylinders: helically wrapped glass-epoxy and boron-epoxy cylinders, and aluminum cylinders overwrapped with boron-epoxy. The helical wrap angle was varied in cylinders of fixed geometry to identify wrapping configurations of minimum imperfection

sensitivity. Sensitivity indices were obtained from the present theory as well as from an extension of existing theory. Agreement between sensitivity indices predicted by the two theories was reasonably good. Computed results for buckling of the three types of cylinders suggest that substantial differences (up to 27 percent) can exist between classical and consistent theory predictions for buckling, depending on the wrapping configuration. The differences are a result of load-induced prebuckling deformations which are retained in consistent buckling theories but are omitted in classical theories.

Sensitivity indices computed for the three types of cylinders suggest that 45° wraps in helically wound glass-epoxy and boron-epoxy shells are desirable. For wraps possessing small imperfection sensitivity, boron-epoxy cylinders are less imperfection-sensitive than glass-epoxy cylinders. The most attractive configuration identified in the study was a circumferentially overwound boron-aluminum shell which was found to have a positive postbuckling slope.

The behavior of fiber-reinforced cylinders was investigated experimentally by conducting compressive buckling tests on twelve 30-inch-diameter glass-epoxy shells with variable wrap configurations. Elastic constants computed from test data were in good agreement with analytical predictions. Depending on wrap configuration, compressive buckling loads varied from 50 to 90 percent of consistent theory predictions. Comparisons of imperfection sensitivity indices with test data show that the indices are in fair agreement with experimental buckling data trends. The theoretical and experimental studies reported herein suggest that

certain fiber orientations can enhance the compressive buckling strength of geometrically similar cylinders due to the fiber configuration's reduced sensitivity to geometric imperfections in the cylinder wall.

IV. INTRODUCTION

The purpose of the dissertation is to investigate the sensitivity of fiber-reinforced cylinders to small imperfections in the geometry of the wall of the cylinder. The development of boron and high-modulus glass fibers as reinforcement suggests that fiber-wound or fiber-reinforced shells possess great technological potential. Recent experience at NASA (refs. 1 to 4) and elsewhere has indicated that the state of the art of these new materials is such that their elastic behavior can be predicted with reasonable engineering accuracy. Furthermore, efficiency studies of cylindrical shells loaded in axial compression (ref. 5) have shown that they are competitive with the best metallic shells as lightweight load-carrying members. Thus, studies of filamentary shells are of current technological interest.

If fibrous shells are ever to be accepted as reliable load-bearing elements, their structural behavior must be thoroughly understood. One of the most important factors in the buckling behavior of a shell is its sensitivity to small deviations from perfect geometry. The sensitivity of axially loaded cylindrical shells to initial imperfections has long been suspected to be a major cause of lack of agreement between theoretical predictions and experimental buckling data for shells loaded in axial compression. Recent tests on carefully manufactured cylindrical specimens (refs. 6 to 8) indicate that shells of near-perfect geometry can develop loads which approach predictions for idealized shells. The problem, however, still remains to find some method of making practical shell structures more predictable and, hence, more reliable.

By the nature of their construction, fiber-reinforced shells usually possess orthotropic material characteristics. In studies of the behavior of orthotropic shells, there is some evidence that, given the proper orthotropy and geometry, orthotropic shells can behave with relatively low sensitivity to small initial imperfections. For example, buckling data for axially loaded longitudinally stiffened cylindrical shells (which can be considered to be a class of orthotropic shells) have been shown by the author to be in good agreement with theoretical predictions for ideal cylinders (ref. 9). Furthermore, postbuckling studies (refs. 10 to 14) have indicated that minimum postbuckling loads for orthotropic cylinders can be much higher than isotropic cylinders with similar radiusthickness ratios. These observations have been used in attempts to predict "knockdown factors" (reductions in theoretical predictions) to correlate buckling theory and experiment (ref. 15). The insensitivity of orthotropic shells has not been established in general and, in fact, imperfection sensitivity of stiffened shells in certain geometric ranges has been noted in references 16 and 17.

An interesting peculiarity of fiber-reinforced shells is the fact that by suitable layering, two-dimensional isotropic relations for the elastic constants of the shell wall can be obtained. Thus, by varying the orientation of fibers in a shell of fixed geometry, one can encounter for a shell with specified length, radius, and total thickness, an isotropic configuration among configurations of varying degrees of orthotropy. Hence, the designer of fiber-reinforced shells, as opposed to metallic shells, has at his disposal an additional degree-of-freedom-orthotropy.

Based on the limited evidence of the reduced sensitivity of certain orthotropic shells to initial imperfections, we are confronted with the following interesting possibility in design. It is conceivable that for certain geometries we can find two fiber-reinforced shells, one possessing orthotropy, the other isotropy, such that the isotropic shell will buckle at a higher load theoretically. However, because of the greater sensitivity of the isotropic shell to initial imperfections, the orthotropic shell practically will carry a higher load and, even more important, may be more predictable in its behavior.

The goal of the present research is to study the relative imperfection sensitivity of fiber-reinforced cylinders in order to identify which fiber configurations are least/sensitive to initial geometric imperfec-The investigation is accomplished by studying the behavior of a perfect shell in its initial postbuckling region. An index of imperfection sensitivity as suggested by Koiter (refs. 16 to 24) is determined by perturbing the shell displacements in the neighborhood of the bifur-The effects of nonlinear displacements induced by loading cation point. prior to buckling are considered. The theory is derived by employing principles of perturbation theory and represents an extension to cylindrical shells of the plate postbuckling theory developed by Stein (ref. 25). Relative values of the sensitivity index are found for helically wrapped cylinders of glass-epoxy, boron-epoxy, and boronaluminum loaded in axial compression. Wrapping configurations were varied to discover configurations of minimum imperfection sensitivity.

A series of compression tests was conducted on twelve glass-epoxy, filament-wound cylinders to investigate experimental buckling behavior. Theoretical imperfection sensitivity trends are compared with the experimental results.

Primes are used to denote ordinary differentiation with respect to the variable x. A subscript preceded by a comma denotes partial differentiation with respect to the subscript.

VI. IMPERFECTION SENSITIVITY INDEX

There are several studies of the sensitivity of shells to initial imperfections available in the literature (see, e.g., refs. 26 and 27). The majority of these studies are restricted by the adoption of an initial imperfection of specified geometry. Practically speaking, however, real initial imperfections have a somewhat random character. An example of this fact is shown in figure 1. Measured radial displacements from perfect geometry are shown for a 10-foot diameter ringstiffened cylindrical shell (ref. 28). The initial radial displacement wi divided by the shell thickness t is plotted against length for various circumferential stations about 6 inches apart. It is evident that considerable judgment and ingenuity is required to represent such initial imperfections analytically. Thus, in the present state of the art, it seems impractical to hope for an analysis which will yield the exact reduction in buckling load for a wide range of realistic imperfection geometries. However, a method of assessing relative sensitivities of shells to initial imperfections does exist.

In his doctoral dissertation, Koiter (ref. 19) proposed a theoretical method of obtaining an estimate of the sensitivity of a broad class of shells to initial imperfections. In the Koiter theory, it is postulated that the sensitivity of a structure to small initial imperfections can be assessed by a knowledge of the perfect structure's behavior in the initial postbuckling region. In his thesis, Koiter demonstrates that for imperfections having the shape of the perfect shell buckling mode,

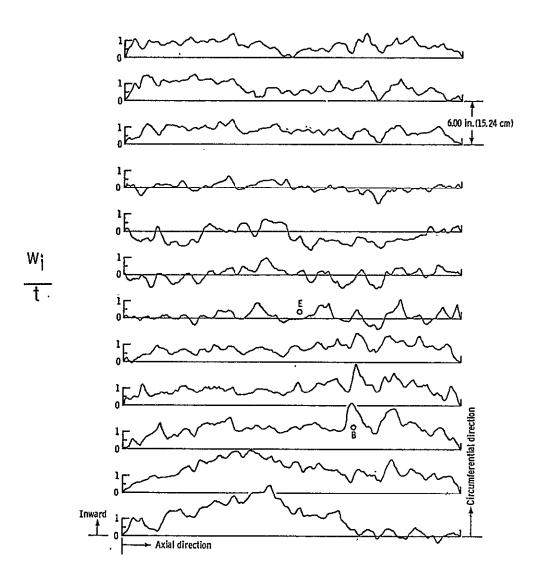

Figure 1.- Real geometry of measured imperfections in a large cylinder (ref. 28).

the sensitivity of the shell could be investigated with a knowledge of either of two fundamental parameters.

These parameters were identified by expanding the applied load λ as a function of a scalar perturbation parameter ξ . The parameter ξ is arbitrary and physically can be considered to be any convenient, suitably small measure of the growth of displacements in the shell just after buckling. The expansion of load in terms of this scalar measure of postbuckling displacement can be written as

$$\lambda = \lambda_{cr} + a\lambda_{cr} + b\lambda_{cr} + b\lambda_{cr}$$

where $\lambda_{\rm Cr}$ is the bifurcation or buckling load. Koiter has demonstrated that when small initial imperfections are taken into account, the relationship between the buckling load of the shell in the presence of the imperfection and the buckling load for a perfect shell is related to the parameters a and b. For example, Koiter has shown for a shell governed by "cubic" behavior (a = 0), the relationship between the buckling load $\lambda_{\rm S}$ in the presence of an initial imperfection of magnitude $\overline{\xi}$ and the buckling load for a perfect shell $\lambda_{\rm Cr}$ is given by

$$\left(1 - \frac{\lambda_s}{\lambda_{cr}}\right)^{3/2} = \frac{3\sqrt{3}}{2} |\vec{\xi}| \sqrt{-b} \left(\frac{\lambda_s}{\lambda_{cr}}\right)$$

The above relationship is restricted to the so-called "classical" theory of buckling in which the effects of deformations prior to buckling are ignored. Recent results (refs. 23 and 24), in which these effects are

considered, also conclude that b is a measure number of the reduction in buckling load due to imperfections.

Thus, depending on the type of shell, either a or b is a fundamental parameter in assessing relative sensitivity to small imperfections, that is, the imperfection sensitivity index. Hence, the goal of employing Koiter's theory to assess imperfection sensitivity is to understand the character of the postbuckling behavior of the structure in the neighborhood of a singularity, namely, the point of buckling. This type of consideration is somewhat analogous to studies in the theory of nonlinear vibrations where one examines the character of singularities in vibrating systems (e.g., refs. 29 and 30). In fact, in this field there is even Poincaré's "index of singularity." Koiter's work relates the character of the singularity occurring at buckling (bifurcation) to the structure's sensitivity to initial imperfections.

VII. DERIVATION OF GOVERNING EQUATIONS

Assumptions

In developing the theoretical estimate of imperfection sensitivity of the cylinder, several basic assumptions are made. The cylinder is assumed to be composed of several orthotropic layers, each with one of its principal axes of orthotropy alined with the cylinder axis. The effects of transverse shear are ignored. At the onset of loading, the cylinder is assumed to be perfectly cylindrical so that its shape is changed only by deformations induced by load. The cylinder is assumed to buckle into a unique buckling mode, so that the behavior of the shell can be investigated in the neighborhood of a bifurcation point. For a cylinder, this restriction precludes consideration of cylinders that "buckle" in an axisymmetric mode. Axisymmetric "buckling" in a cylinder is simply unchecked growth of the axisymmetric deformations induced by loading and is often described as collapse rather than buckling. Since no bifurcation occurs, the present theory cannot assess relative imperfection sensitivity for this phenomenon.

The theory is developed by adopting the Koiter parameters to obtain the sensitivity index of a perfect cylinder. The development of the theory differs from that existing in the literature (refs. 16 to 24) in that the index is identified by employing perturbation techniques similar to those of reference 25. Nonlinear equilibrium equations formulated from Donnell-von Karman strain displacement relations are perturbed about the bifurcation point to find equations governing the behavior of the

shell in the initial postbuckling region. The perturbation is shown to produce secular terms which are constrained to vanish. The constraint conditions yield relationships between the sensitivity index and the buckling mode. The sensitivity index is then computed by using the constraint condition together with a suitable definition of the perturbation parameter.

Equilibrium Equations

Nonlinear equilibrium equations are formulated using the Donnellvon Karman strain displacement relations. Under the assumptions, the virtual work expression for a multilayered orthotropic cylinder loaded in axial compression can be written as follows:

$$\delta \Pi = \int_{0}^{A} \int_{0}^{2\pi R} (N_{x} \delta \epsilon_{x} + N_{y} \delta \epsilon_{y} + N_{xy} \delta \gamma_{xy} + M_{x} \delta \kappa_{x} + M_{y} \delta \kappa_{y} + M_{xy} \delta \kappa_{xy}) dx dy$$

$$+ \int_{0}^{2\pi R} \lambda \delta u \begin{vmatrix} A \\ 0 \end{vmatrix} dy = 0$$
(1)

where

$$N_{x} = C_{11}\epsilon_{x} + C_{12}\epsilon_{y} + K_{11}\kappa_{x} + K_{12}\kappa_{y}$$

$$N_{y} = C_{12}\epsilon_{x} + C_{22}\epsilon_{y} + K_{12}\kappa_{x} + K_{22}\kappa_{y}$$

$$N_{xy} = C_{66}\gamma_{xy} + K_{66}\kappa_{xy}$$

$$M_{x} = K_{11}\epsilon_{x} + K_{12}\epsilon_{y} + D_{11}\kappa_{x} + D_{12}\kappa_{y}$$

$$M_{y} = K_{12}\epsilon_{x} + K_{22}\epsilon_{y} + D_{12}\kappa_{x} + D_{22}\kappa_{y}$$

$$M_{xy} = K_{66}\gamma_{xy} + D_{66}\kappa_{xy}$$

$$M_{xy} = K_{66}\gamma_{xy} + D_{66}\kappa_{xy}$$
(2)

with

$$\epsilon_{x} = u_{,x} + \frac{1}{2} w_{,x}^{2}$$
 $\kappa_{x} = -w_{,xx}$

$$\epsilon_{y} = v_{,y} + \frac{w}{R} + \frac{1}{2} w_{,y}^{2}$$
 $\kappa_{y} = -w_{,yy}$

$$\kappa_{y} = -w_{,yy}$$

$$\kappa_{xy} = -2w_{,xy}$$
(3)

In equations (2), $C_{i,j}$, $D_{i,j}$, and $K_{i,j}$ are structural stiffnesses of the multilayered wall associated with extension, bending and coupling between bending and extension, respectively. If the stress-strain relations for the ith cylinder layer are written as

$$\sigma_{x}^{i} = \frac{E_{x}^{i}}{1 - \mu_{x}^{i}\mu_{y}^{i}} \left(\epsilon_{x}^{i} + \mu_{y}^{i}\epsilon_{y}^{i} \right)$$

$$\sigma_{y}^{i} = \frac{E_{y}^{i}}{1 - \mu_{x}^{i}\mu_{y}^{i}} \left(\epsilon_{y}^{i} + \mu_{x}^{i}\epsilon_{x}^{i} \right)$$

$$\tau_{xy}^{i} = G_{xy}^{i}\gamma_{xy}^{i}$$

$$(4)$$

then, the structural stiffnesses can be defined by the following integrals:

$$C_{11} = \int_{\text{wall}} \frac{E_{x}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, dz \qquad C_{12} = \int_{\text{wall}} \frac{\mu_{y}^{i} E_{x}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, dz \qquad C_{22} = \int_{\text{wall}} \frac{E_{y}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, dz$$

$$K_{11} = \int_{\text{wall}} \frac{E_{x}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, z \, dz \qquad K_{12} = \int_{\text{wall}} \frac{\mu_{y}^{i} E_{x}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, z \, dz \qquad K_{22} = \int_{\text{wall}} \frac{E_{y}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, z \, dz$$

$$D_{11} = \int_{\text{wall}} \frac{E_{x}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, z^{2} dz \qquad D_{12} = \int_{\text{wall}} \frac{\mu_{y}^{i} E_{x}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, z^{2} dz \qquad D_{22} = \int_{\text{wall}} \frac{E_{y}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, z^{2} dz$$

$$D_{22} = \int_{\text{wall}} \frac{E_{y}^{i}}{1 - \mu_{x}^{i} \mu_{y}^{i}} \, z^{2} dz$$

The integrals appearing in equations (5) can be evaluated for an arbitrary reference surface by using equations (83) and (85) of reference 31. The elastic constants for fiber-reinforced structures appearing in equations (4) can be predicted analytically from the constituent properties of the fiber and matrix. The constants for a layer in which the fibers are unidirectional can be obtained from any of references 32 to 35. For layers with fibers oriented at angles $\pm \alpha$ (see fig. 2), an "equivalent" orthotropic layer is defined through compatibility considerations and the transformation equations of orthotropic elasticity (see refs. 35 to 37). The formulae employed herein are summarized in appendix B of reference 1.

Equation (1) can be expressed as a function of the displacement variables u, v, and w. Integration by parts yields the following equilibrium equations which are valid in the postbuckling region:

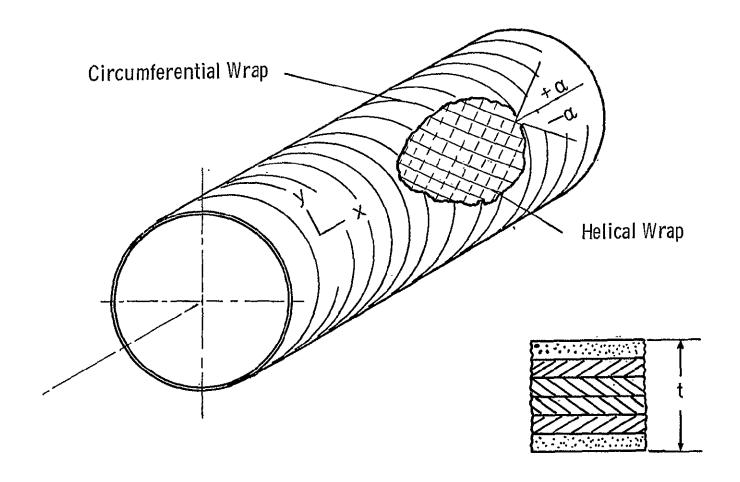

Figure 2.- Geometry of fiber-reinforced cylinders.

The boundary conditions resulting from the variations, with the load specified and the cylinder supported at the ends, can be written as

$$N_{x} + \lambda = 0$$

$$N_{xy} = 0 \quad \text{or} \quad v = 0$$

$$M_{x} = 0 \quad \text{or} \quad w_{,x} = 0$$

$$w = 0$$
(7)

Perturbation Procedure

Following the Koiter procedure, the displacements are expanded as

$$u = u_0(\xi) + u_1 \xi + u_2 \xi^2 + \dots$$

$$v = v_0(\xi) + v_1 \xi + v_2 \xi^2 + \dots$$

$$w = w_0(\xi) + w_1 \xi + w_2 \xi^2 + \dots$$
(8)

where the subscript 0 denotes the axisymmetric state of deformation induced by load and \$\xi\$ is the perturbation parameter.

The applied compressive load λ is expanded as

$$\lambda = \lambda_{er} + a\lambda_{er}\xi + b\lambda_{er}\xi^2 + \dots$$
 (9)

where $\lambda_{\rm cr}$ is the applied load at buckling. At this point, it should be observed that Koiter's work was based on classical buckling analysis so that the dependence of the axisymmetric deformations (u_0, v_0, w_0) on ξ is not clearly noted. Fitch (ref. 24) has recently generalized Koiter's work to include the effects of deformations prior to buckling. In Fitch's work, the dependence of the axisymmetric deformations on ξ can be found by expanding these deformations in a Taylor series about the buckling load $\lambda_{\rm cr}$. Thus,

$$u_{o} = u_{o}^{*} + (\lambda - \lambda_{cr})u_{o,\lambda}^{*} + \frac{1}{2}(\lambda - \lambda_{cr})^{2} u_{o,\lambda\lambda}^{*} + \dots$$

$$v_{o} = v_{o}^{*} + (\lambda - \lambda_{cr})v_{o,\lambda}^{*} + \frac{1}{2}(\lambda - \lambda_{cr})^{2} v_{o,\lambda\lambda}^{*} + \dots$$

$$v_{o} = w_{o}^{*} + (\lambda - \lambda_{cr})v_{o,\lambda}^{*} + \frac{1}{2}(\lambda - \lambda_{cr})^{2} w_{o,\lambda\lambda}^{*} + \dots$$

$$(10)$$

where the * denotes quantities evaluated at $\lambda = \lambda_{cr}$. For example,

$$M_{\star}^{O}$$
 = $\frac{9 \times 9 y}{9 \times 6}$ $y = y^{GL}$

Using equations (9) and (10)

$$u = u_{0}^{*} + (a\lambda_{cr}u_{0,\lambda}^{*} + u_{1})\xi + \left(\frac{1}{2}a^{2}\lambda_{cr}^{2}u_{0,\lambda\lambda}^{*} + b\lambda_{cr}u_{0,\lambda}^{*} + u_{2}\right)\xi^{2} + \cdots$$

$$v = v_{0}^{*} + (a\lambda_{cr}v_{0,\lambda}^{*} + v_{1})\xi + \left(\frac{1}{2}a^{2}\lambda_{cr}^{2}v_{0,\lambda\lambda}^{*} + b\lambda_{cr}v_{0,\lambda}^{*} + v_{2}\right)\xi^{2} + \cdots$$

$$w = w_{0}^{*} + (a\lambda_{cr}v_{0,\lambda}^{*} + v_{1})\xi + \left(\frac{1}{2}a^{2}\lambda_{cr}^{2}v_{0,\lambda\lambda}^{*} + b\lambda_{cr}v_{0,\lambda}^{*} + v_{2}\right)\xi^{2} + \cdots$$

$$(11)$$

Zeroth Perturbation

If equations (11) are substituted into the equilibrium equations (6) and the boundary conditions (7), a series of equations corresponding to powers of § are obtained. The equations corresponding to the zeroth power of § can be written as follows

$$\xi^{O}$$
: $N_{X_{O}}^{*t} = 0$ (12a)

$$N_{XY_O}^{*1} = 0 \tag{12b}$$

$$- M_{X_O}^{*,i} + \frac{N_{Y_O}^*}{R} - N_{X_O}^* N_O^{*,i} = 0$$
 (12c)

with boundary conditions

$$N_{\infty}^* + \lambda_{cr} = 0 \tag{13a}$$

$$N_{xy_0}^* = 0 \text{ or } v_0^* = 0$$
 (13b)

$$w_0^* = 0$$
 (13c)

with

where the prime denotes ordinary differentiation with respect to x.

The stress resultants of equations (12) and (13) are defined by substituting equations (14) into the constitutive relations of equations (2).

Equations (12) and (13) can be identified as equations determining the axisymmetric deformations occurring in the cylinder prior to buckling. The asterisk indicates that the deformations resulting from these equations must be evaluated at the inception of buckling, that is, at $\lambda = \lambda_{\rm cr}.$

Solutions to equations (12) can be obtained by integrating equation (12a) and applying boundary condition (13a) so that

$$N_{x_{O}}^{*} = -\lambda_{cr}$$
 (15)

From the definition of $\mathbb{N}_{\mathbf{x}_0}^*$, it follows that

$$\epsilon_{x_0}^* = u_0^{*'} + \frac{1}{2} (w_0^{*'})^2 = \frac{K_{11}}{C_{11}} w_0^{*'} - \frac{C_{12}}{C_{11}} \frac{w_0^*}{R} - \frac{\lambda_{cr}}{C_{11}}$$
 (16)

Integration of equation (12b) together with either of boundary conditions (13b) imply that both v_0^* and $N_{xy_0}^*$ are zero everywhere. Substitution

of equation (16) into equation (12c) yields the following ordinary differential equation in w_0^* ,

$$\left(D_{11} - \frac{K_{11}^{2}}{C_{11}}\right) w_{0}^{* ""} + \left[\frac{2}{R} \left(\frac{K_{11}C_{12}}{C_{11}} - K_{12}\right) + \lambda_{cr}\right] w_{0}^{*"} + \frac{1}{R^{2}} \left(C_{22} - \frac{C_{12}^{2}}{C_{11}}\right) w_{0}^{*}$$

$$= \frac{1}{R} \frac{C_{12}}{C_{11}} \lambda_{cr} \qquad (17)$$

For simply supported shells $(M_{X_0}^* = 0)$ with boundary conditions applied at $\overline{x} = \pm A/2$ when A is the cylinder length, the solution of (17) can be written as

$$w_0^* = F_1 \sinh \beta \overline{x} \sin \gamma \overline{x} + F_2 \cosh \beta \overline{x} \cos \gamma \overline{x} + \lambda_{cr}^P$$
 (18)

where

$$\beta = \sqrt{\frac{1}{2R} \sqrt{\frac{c_{11} \ c_{22} - c_{12}^2}{D_{11} \ c_{11} - K_{11}^2}} - \frac{K_{11}c_{12} - K_{12}c_{11} + \frac{\lambda_{cr}}{2} \ c_{11}R}}{D_{11}c_{11} - K_{11}^2}}$$

$$\gamma = \sqrt{\frac{1}{2R} \left(\sqrt{\frac{c_{11} \ c_{22} - c_{12}^2}{c_{11} - \kappa_{11}^2}} + \frac{\kappa_{11} c_{12} - \kappa_{12} c_{11} + \frac{\lambda_{cr}}{2} c_{11} R}{c_{11} - \kappa_{11}^2} \right)}.$$

$$P_1 = \frac{c_{12}R}{c_{11}c_{22} - c_{12}^2}$$

$$F_{1} = \frac{G_{1}\cosh \frac{\beta A}{2}\cos \frac{\gamma A}{2} - G_{2}\sinh \frac{\beta A}{2}\sin \frac{\gamma A}{2}}{2\left(D_{11} - \frac{K_{11}^{2}}{C_{11}}\right)\beta\gamma\left(\sinh^{2}\frac{\beta A}{2}\sin^{2}\frac{\gamma A}{2} + \cosh^{2}\frac{\beta A}{2}\cos^{2}\frac{\gamma A}{2}\right)}$$

$$G_{2}\cosh \frac{\beta A}{2}\cos \frac{\gamma A}{2} + G_{1}\sinh \frac{\beta A}{2}\sin \frac{\gamma A}{2}$$

$$F_{2} = \frac{C_{11} - \frac{K_{11}^{2}}{C_{11}} \beta \gamma \left(\sinh^{2} \frac{\beta A}{2} \sin^{2} \frac{\gamma A}{2} + \cosh^{2} \frac{\beta A}{2} \cos^{2} \frac{\gamma A}{2} \right)}{2 \left(\sin^{2} \frac{\beta A}{2} \sin^{2} \frac{\gamma A}{2} + \cosh^{2} \frac{\beta A}{2} \cos^{2} \frac{\gamma A}{2} \right)}$$

with

$$G_{\perp} = \lambda_{cr} \left[\frac{K_{11}}{C_{11}} + R \frac{C_{12}}{C_{11}} \left(\frac{D_{11}C_{11} - K_{12}^2}{C_{11}C_{22} - C_{12}^2} \right) (\beta^2 - \gamma^2) \right]$$

$$G_2 = 2\beta\gamma R \frac{c_{12}}{c_{11}} \left(\frac{c_{11}c_{11} - \kappa_{12}^2}{c_{11}c_{22} - c_{12}^2} \right)$$

For clamped boundary conditions, the radial displacement w* is given by (18) with

$$F_{1} = \lambda_{cr} P_{1}$$

$$\beta \sin \frac{\beta A}{2} \cos \frac{\gamma A}{2} - \gamma \cosh \frac{\beta A}{2} \sin \frac{\gamma A}{2}$$

$$\beta \sin \frac{\gamma A}{2} \cos \frac{\gamma A}{2} + \gamma \sinh \frac{\beta A}{2} \cosh \frac{\beta A}{2}$$

$$F_{2} = -\lambda_{cr}P_{1} \xrightarrow{\gamma \text{A} cos \frac{\gamma A}{2} + \beta cosh \frac{\beta A}{2} sin \frac{\gamma A}{2}}$$

$$\beta sin \frac{\gamma A}{2} cos \frac{\gamma A}{2} + \gamma sinh \frac{\beta A}{2} cosh \frac{\beta A}{2}$$
(19)

Note, in general, that quantities such as $w_{0,\lambda}^*$ can be found from equations (18) and (19) by replacing $\lambda_{\rm cr}$ by λ , performing the indicated partial differentiation and evaluating the result at $\lambda = \lambda_{\rm cr}$. For the quantity $w_{0,x\lambda}^*$, the result can be written as

$$\mathbf{w}_{0,\mathbf{x}\lambda}^{*} = \cosh \beta \overline{\mathbf{x}} \sin \gamma \overline{\mathbf{x}} (\mathbf{F}_{1}\beta - \mathbf{F}_{2}\gamma)_{,\lambda} + \sinh \beta \overline{\mathbf{x}} \cos \gamma \overline{\mathbf{x}} (\mathbf{F}_{1}\gamma + \mathbf{F}_{2}\beta)_{,\lambda}$$

$$+ \overline{\mathbf{x}} \sinh \beta \overline{\mathbf{x}} \sin \gamma \overline{\mathbf{x}} \left[\beta_{,\lambda} (\mathbf{F}_{1}\beta - \mathbf{F}_{2}\gamma) - \gamma_{,\lambda} (\mathbf{F}_{1}\gamma + \mathbf{F}_{2}\beta) \right]$$

$$+ \overline{\mathbf{x}} \cosh \beta \overline{\mathbf{x}} \cos \gamma \overline{\mathbf{x}} \left[\beta_{,\lambda} (\mathbf{F}_{1}\gamma + \mathbf{F}_{2}\beta) + \gamma_{,\lambda} (\mathbf{F}_{1}\beta - \mathbf{F}_{2}\gamma) \right] \qquad (20)$$

with '

$$\gamma_{,\lambda} = \frac{c_{11}}{8\gamma(D_{11}c_{11} - K_{11}^2)}$$

$$\beta_{,\lambda} = \frac{c_{11}}{8\beta(D_{11}c_{11} - K_{11}^2)}$$

For simple support boundary conditions, if

$$F_1 = \frac{G_{12}}{G}$$
 and $F_2 = \frac{G_{21}}{G}$

$$\begin{split} F_{2,\lambda} &= -\frac{G_{1,\lambda}}{G} \sinh \frac{\beta A}{2} \sin \frac{\gamma A}{2} - \frac{G_{2,\lambda}}{G} \cosh \frac{\beta A}{2} \cos \frac{\gamma A}{2} \\ &+ \frac{A}{2G} \cosh \frac{\beta A}{2} \sin \frac{\gamma A}{2} (G_{2}\gamma_{,\lambda} - G_{1}\beta_{,\lambda}) - \frac{A}{2G} \sinh \frac{\beta A}{2} \cos \frac{\gamma A}{2} (G_{1}\gamma_{,\lambda} + G_{2}\beta_{,\lambda}) \\ &+ \frac{2G_{21}}{G^{2}} (\gamma \beta)_{,\lambda} \left(\sinh^{2} \frac{\beta A}{2} \sin^{2} \frac{\gamma A}{2} + \cosh^{2} \frac{\beta A}{2} \cos^{2} \frac{\gamma A}{2} \right) \\ &+ \frac{2G_{21}}{G^{2}} \gamma \beta A \left(\beta_{,\lambda} \sinh \frac{\beta A}{2} \cosh \frac{\beta A}{2} - \gamma_{,\lambda} \sin \frac{\gamma A}{2} \cos \frac{\gamma A}{2} \right) \end{split}$$

 $+\frac{A}{2a}\sinh\frac{\beta A}{2}\cos\frac{\gamma A}{2}(G_1\beta_{,\lambda}-G_2\gamma_{,\lambda})-\frac{A}{2a}\cosh\frac{\beta A}{2}\sin\frac{\gamma A}{2}(G_1\gamma_{,\lambda}+G_2\beta_{,\lambda})$

 $F_{1,\lambda} = \frac{G_{1,\lambda}}{C} \cosh \frac{\beta A}{2} \cos \frac{\gamma A}{2} - \frac{G_{2,\lambda}}{C} \sinh \frac{\beta A}{2} \sin \frac{\gamma A}{2}$

 $-\frac{2G_{12}}{2}(\gamma\beta)$, $\sqrt{\sinh^2 \frac{\beta A}{2} \sin^2 \frac{\gamma A}{2} + \cosh^2 \frac{\beta A}{2} \cos^2 \frac{\gamma A}{2}}$

 $-\frac{2G_{12}}{2} \gamma \beta A \left(\beta_{\lambda} \sinh \frac{\beta A}{2} \cosh \frac{\beta A}{2} - \gamma_{\lambda} \sin \frac{\gamma A}{2} \cos \frac{\gamma A}{2}\right).$

with

$$G_{1,\lambda} = P_{1} \left[\beta^{2} - \gamma^{2} + 2\lambda_{er}(\beta\beta, \lambda - \gamma\gamma, \lambda) - \frac{K_{11}}{D_{11}C_{11} - K_{11}^{2}} \right]$$

$$G_{2,\lambda} = P_{1} \left[2\lambda_{er}(\beta\gamma), \lambda + 2\gamma\beta \right]$$

For clamped boundary conditions, if

$$F_1 = \frac{\lambda_{cr} P_1 G_{12}}{G}$$
 and $F_2 = -\frac{\lambda_{cr} P_1 G_{21}}{G}$

$$F_{1,\lambda} = \frac{P_1 G_{12}}{G} + \frac{\lambda_{cr} P_1}{G} \left(\beta_{,\lambda} \sinh \frac{\beta A}{2} \cos \frac{\gamma A}{2} - \gamma_{,\lambda} \cosh \frac{\beta A}{2} \sin \frac{\gamma A}{2} \right)$$

$$- + \frac{A}{2} \frac{\lambda_{cr} P_1}{G} \left[\cosh \frac{\beta A}{2} \cos \frac{\gamma A}{2} (\beta \beta_{,\lambda} - \gamma \gamma_{,\lambda}) - \sinh \frac{\beta A}{2} \sin \frac{\gamma A}{2} (\beta \gamma)_{,\lambda} \right]$$

$$- \frac{\lambda_{cr} P_1 G_{12}}{2G^2} (\beta_{,\lambda} \sin \gamma A + A \beta \gamma_{,\lambda} \cos \gamma A + \gamma_{,\lambda} \sinh \beta A + A \gamma \beta_{,\lambda} \cosh \beta A)$$

ß.

(22)

$$\begin{split} F_{2,\lambda} &= -\frac{P_{1}G_{21}}{G} - \frac{\lambda_{cr}P_{1}}{G} \left(\beta_{,\lambda} \cosh \frac{\beta A}{2} \sin \frac{\gamma A}{2} + \gamma_{,\lambda} \sinh \frac{\beta A}{2} \cos \frac{\gamma A}{2}\right) \\ &- \frac{A}{2} \frac{\lambda_{cr}P_{1}}{G} \left[\sinh \frac{\beta A}{2} \sin \frac{\gamma A}{2} (\beta \beta_{,\lambda} - \gamma \gamma_{,\lambda}) + \cosh \frac{\beta A}{2} \cos \frac{\gamma A}{2} (\beta \gamma)_{,\lambda} \right] \\ &+ \frac{\lambda_{cr}P_{1}G_{21}}{2G^{2}} (\beta_{,\lambda} \sin \gamma A + A\beta \gamma_{,\lambda} \cos \gamma A + \gamma_{,\lambda} \sinh \beta A + A\gamma \beta_{,\lambda} \cosh \beta A) \end{split}$$

It should be noted that equations (18) through (22) were developed by exploiting symmetry of the boundary conditions using a coordinate \bar{x} with origin at the middle of the cylinder. For subsequent developments, a more convenient coordinate is \bar{x} whose origin is at the end of the cylinder. Equations (18) through (20) may be written for this coordinate by using the transformation $\bar{x} = x - A/2$.

First Perturbation

The equations corresponding to the first power of & can be written as follows:

with boundary conditions

$$N_{X_{1}} = 0$$

$$v_{1} = 0 \quad \text{or} \quad N_{XY_{1}} = 0$$

$$w_{1} = 0$$

$$M_{X_{1}} = 0 \quad \text{or} \quad w_{1,x} = 0$$

$$(24)$$

In equations (23) and (24) and subsequent perturbations

$$\epsilon_{x_{i}} = u_{i,x} + w_{0,x}^{*} w_{i,x}$$

$$\epsilon_{y_{i}} = v_{i,y} + \frac{w_{i}}{R}$$

$$\gamma_{xy_{i}} = u_{i,y} + v_{i,x} + w_{0,x}^{*} w_{i,y}$$

$$\kappa_{x_{i}} = -w_{i,xx}$$

$$\kappa_{y_{i}} = -w_{i,yy}$$

$$\kappa_{xy_{i}} = -2w_{i,xy}$$
(25)

and the corresponding stress resultants are obtained by substituting equations (25) into the constitutive relations (2).

To obtain equations (23), the equilibrium equations resulting from the zeroth perturbation (eqs. (12)), were used to eliminate terms such as $a\lambda_{\rm Cr}N_{\rm X}^*$, obtained from the perturbation. Also in obtaining the boundary conditions exploitation was made of the fact that terms

having the functional form $a\lambda_{\rm cr} f_{\rm o}^*$, vanish at the boundary if $f_{\rm o}^*$ is zero there. Equations (23) and (24) are similar to the usual equations governing buckling of a prestressed cylinder except for the absence of a free buckling parameter. The buckling parameter is absent since, in the present problem, the displacements of the shell have been expanded about a single, known point of bifurcation. Thus, as opposed to the usual buckling problem in which a multitude of eigenvectors are possible solutions, only one eigenvector is an admissible solution of (23) - namely that corresponding to $N_{\rm X_O}^* = -\lambda_{\rm cr}$. If both the buckling load $\lambda_{\rm cr}$ as well as the number of circumferential waves n in the buckle pattern are established by a conventional buckling analysis (e.g., ref. 38) equations (23) and (24) can be converted into a set of ordinary simultaneous differential equations and boundary conditions by the following substitution:

$$u_{1} = \overline{U}_{1}(x) \cos \frac{ny}{R}$$

$$v_{1} = \overline{V}_{1}(x) \sin \frac{ny}{R}$$

$$w_{1} = \overline{W}_{1}(x) \cos \frac{ny}{R}$$
(26)

As was done in reference 38, the eigenvector corresponding to $N_{X_0}^* = -\lambda_{cr}$ can be found by the method of finite differences and determinant plotting. The components of the resulting eigenvector can be expressed as

$$u_{1} = c_{1}U_{1}(x) \cos \frac{ny}{R}$$

$$v_{1} = c_{1}V_{1}(x) \sin \frac{ny}{R}$$

$$w_{1} = c_{1}W_{1}(x) \cos \frac{ny}{R}$$
(27)

where c_{l} is an arbitrary constant and U_{l} , V_{l} , and W_{l} are suitably normalized components.

Second Perturbation

The equations corresponding to the second power of ξ can be written as follows:

$$N_{x_{2},x} + N_{xy_{2},x} = -a\lambda_{cr} \left[c_{11}(w_{0,x\lambda}^{*} w_{1,x})_{,x} + c_{66}w_{0,x\lambda}^{*} w_{1,yy} \right] - \frac{1}{2} (c_{11} w_{1,x}^{2} + c_{12} w_{1,y}^{2})_{,x} - c_{66}(w_{1,x}w_{1,y})_{,y}$$
(28a)

$$N_{xy_{2},x} + N_{y_{2},y} = -a\lambda_{cr} \left[c_{66}(w_{0}^{*},x_{\lambda} w_{1,y})_{,x} + c_{12} w_{0}^{*},x_{\lambda} w_{1,xy} \right]$$
$$-\frac{1}{2}(c_{12} w_{1,x}^{2} + c_{22} w_{1,y}^{2})_{,y} - c_{66}(w_{1,x}w_{1,y})_{,x}$$
(28b)

$$- M_{X_{2},XX} - 2M_{XY_{2},XY} - M_{Y_{2},YY} + \frac{N_{Y_{2}}}{R} - N_{X_{0}}^{*} w_{2,XX} - N_{X_{2}} w_{0,XX}^{*} - N_{Y_{0}}^{*} w_{2,YY}$$

$$= a\lambda_{cr} \left[N_{X_{1}} w_{0,XX}^{*} + N_{X_{0}}^{*}, \lambda w_{1,XX} + N_{Y_{0}}^{*}, \lambda w_{1,YY} + C_{11}w_{0,X}^{*}, x\lambda w_{0,XX}^{*} w_{1,X} - \frac{C_{12}}{R} w_{0,X}^{*}, x\lambda w_{1,X} \right]$$

$$+ K_{11} \left(w_{0,XX}^{*} w_{1,X} \right)_{,XX} + K_{12}w_{0,XX}^{*} w_{1,XYY} + 2K_{66} \left(w_{0,XX}^{*} w_{1,Y} \right)_{,XY} \right] + \frac{1}{2} \left(K_{11} w_{1,X}^{2} + K_{22} w_{1,Y}^{2} \right)_{,YY} + 2K_{66} \left(w_{1,X}^{*} w_{1,Y} \right)_{,XY}$$

$$+ K_{12} w_{1,X}^{2} + C_{22} w_{1,Y}^{2} \right) + \frac{1}{2} \left(C_{11} w_{1,X}^{2} + C_{12} w_{1,Y}^{2} \right)_{,YY} + 2K_{66} \left(w_{1,X}^{*} w_{1,Y} \right)_{,XY}$$

$$+ N_{X_{1}} w_{1,XX} + 2N_{XY_{1}} w_{1,XY} + N_{Y_{1}} w_{1,YY}$$

$$(28e)$$

with boundary conditions.

$$N_{x_{2}} + \frac{1}{2} C_{11} w_{1,x}^{2} + \frac{1}{2} C_{12} w_{1,y}^{2} = 0$$

$$N_{xy_{2}} + C_{66} w_{1,x} w_{1,y} = 0 \text{ or } v_{2} = 0$$

$$w_{2} = 0$$

$$M_{x_{2}} + \frac{1}{2} K_{11} w_{1,x}^{2} + \frac{1}{2} K_{12} w_{1,y}^{2} = 0 \text{ or } w_{2,x} = 0$$

$$(29)$$

Equations (28) and (29) can be converted into a set of ordinary simultaneous differential equations and boundary conditions by the following substitutions

$$u_{2} = U_{20}(x) + U_{21}(x) \cos \frac{ny}{R} + U_{22}(x) \cos \frac{2ny}{R}$$

$$v_{2} = V_{21}(x) \sin \frac{ny}{R} + V_{22}(x) \sin \frac{2ny}{R}$$

$$w_{2} = W_{20}(x) + W_{21}(x) \cos \frac{ny}{R} + W_{22}(x) \cos \frac{2ny}{R}$$
(30)

Since the differential equations of (28) are linear, solutions corresponding to each set of U_{2i} , V_{2i} , and W_{2i} (i = 0,1,2) can be superposed. However, if the particular solution for U_{2l} , V_{2l} , and W_{2l} is sought by algebraic means from equations (28) and (29), certain difficulties are encountered. If equations (28) and a set of boundary conditions from equation (29) are cast in finite-difference form after

substitution of (30), the resulting simultaneous algebraic equations can be written in matrix notation as

$$A_{21}Z_{21} = a\lambda_{cr}c_1 D_{21}$$
 (31)

where Z_{21} is a column vector whose components are U_{21} , V_{21} , W_{21} , and M_{21} evaluated at each difference station and D_{21} is a column vector containing elements corresponding to the terms multiplied by a on the right-hand side of equations (28) and (29). Because the trigonometric function associated with U_{21} , V_{21} , and W_{21} has the argument ny/R, the determinant of A_{21} has a form identical to that used in determining the buckling load λ_{cr} . Hence,

$$\det A_{21} = 0$$
 (32)

which demonstrates that the particular solution resulting from (31) is a secular term which must be removed from the perturbation. A condition for removal of the secular term is the requirement that

$$A_{21}Z_{21} = a\lambda_{cr} D_{21} = 0$$
 (33)

If Z_{21} is identified as the eigenvector Z_1 corresponding to the solution of equations (23) and (24), then the desired condition for removal of the secular terms is

$$A_1Z_1 = A_{21}Z_{21} = 0 = a\lambda_{cr} D_{21}$$

or

$$Z_1^T A_{21} Z_1 = a \lambda_{er} c_1 Z_1^T D_{21} = 0$$
 (34)

where Z_1^T is the transpose of Z_1 . Since Z_1^T D_{21} is finite and λ_{cr} and c_1 must be finite for buckling to occur, it follows that

$$a = 0 (35) .$$

Thus the only admissible solution corresponding to the functions U_{21} , V_{21} , and V_{21} is the solution to the homogeneous system

$$A_{21}Z_{21} = 0$$

Hence, the general solution to equations (28) and (29) with a = 0 becomes

$$u_{2} = U_{20}(x) + c_{2}U_{1}(x) \cos \frac{ny}{R} + U_{22}(x) \cos \frac{2ny}{R}$$

$$v_{2} = c_{2}V_{1}(x) \sin \frac{ny}{R} + V_{22}(x) \sin \frac{2ny}{R}$$

$$v_{3} = W_{20}(x) + c_{2}W_{1}(x) \cos \frac{ny}{R} + W_{22}(x) \cos \frac{2ny}{R}$$
(36)

where c_2 is an arbitrary constant and U_1 , V_1 , and W_1 are the normalized components of the buckling eigenvector (see eq. (27)).

Third Perturbation

If a = 0, the equations corresponding to the third power of § can be written as follows

$$N_{x_{3},x} + N_{xy_{3},y} = -b\lambda_{cr} \left[c_{11}(w_{0,x\lambda}^{*} w_{1,x})_{,x} + c_{66} w_{0,x\lambda}^{*} w_{1,yy} \right]$$

$$- \left[c_{11}(w_{1,x} w_{2,x})_{,x} + c_{12}(w_{1,y} w_{2,y})_{,x} + c_{66}(w_{1,x} w_{2,y} + w_{1,y} w_{2,x})_{,y} \right]$$

$$\begin{split} \mathbb{N}_{xy_3,x} + \mathbb{N}_{y_3,y} &= -b\lambda_{cr} \bigg[c_{66}(w_{0,x\lambda}^* w_{1,y})_{,x} + c_{12} w_{0,x\lambda}^* w_{1,xy} \bigg] \\ &- \bigg[c_{66}(w_{1,x} w_{2,y} + w_{1,y} w_{2,x})_{,x} + c_{12}(w_{1,x} w_{2,x})_{,y} + c_{22}(w_{1,y} w_{2,y})_{,y} \bigg] \end{split}$$

$$- M_{x_{3},xx} - 2M_{xy_{3},xy} - M_{y_{3},yy} + \frac{N_{y_{3}}}{R} - N_{x_{0}}^{*} w_{3,xx} - N_{x_{3}} w_{0,xx}^{*} - N_{y_{0}}^{*} w_{3,yy}$$

$$= b\lambda_{cr} \left[N_{x_{0},\lambda}^{*} w_{1,xx} + N_{x_{1}} w_{0,xx}^{*} + N_{y_{0},\lambda}^{*} w_{1,yy} + C_{11} w_{0,xx}^{*} w_{0,x\lambda}^{*} w_{1,x} - \frac{C_{12}}{R} w_{0,x\lambda}^{*} w_{1,x} \right]$$

$$+ K_{11} (w_{0,x\lambda}^{*} w_{1,x})_{,xx} + 2K_{66} (w_{0,x\lambda}^{*} w_{1,y})_{,xy} + K_{12} (w_{0,x\lambda}^{*} w_{1,x})_{,yy} + K_{11} (w_{1,x} w_{2,x})_{,xx}$$

$$+ K_{12} \left[(w_{1,y} w_{2,y})_{,xx} + (w_{1,x} w_{2,x})_{,yy} \right] + K_{22} (w_{1,y} w_{2,y})_{,yy} + 2K_{66} (w_{1,x} w_{2,y})$$

$$+ w_{1,y} w_{2,x})_{,xy} + (C_{11} w_{1,x} w_{2,x} + C_{12} w_{1,y} w_{2,y})_{w_{0,xx}} - \frac{1}{R} (C_{12} w_{1,x} w_{2,x})$$

(37)

$$+ c_{22} w_{1,y} w_{2,y} + \frac{w_{1,xx}}{2} (c_{11} w_{1,x}^2 + c_{12} w_{1,y}^2) + \frac{w_{1,yy}}{2} (c_{12} w_{1,x}^2 + c_{22} w_{1,y}^2) + \frac{w_{1,yy}}{2} (c_{12} w_{1,x}^2 + c_{22} w_{1,y}^2) + 2c_{66} w_{1,x} w_{1,y} w_{1,xy} + N_{x_1} w_{2,xx} + N_{x_2} w_{1,xx}$$

$$+ N_{y_1} w_{2,yy} + N_{y_2} w_{1,yy} + 2N_{xy_1} w_{2,xy} + 2N_{xy_2} w_{1,xy}$$

with boundary conditions

Equations (37) and (38) can be converted into a set of ordinary simultaneous differential equations and boundary conditions by the following substitutions:

$$u_{3} = U_{30}(x) + U_{31}(x) \cos \frac{ny}{R} + U_{32}(x) \cos \frac{2ny}{R} + U_{33}(x) \cos \frac{3ny}{R}$$

$$v_{3} = V_{33}(x) \sin \frac{ny}{R} + V_{32}(x) \sin \frac{2ny}{R} + V_{33} \sin \frac{3ny}{R}$$

$$w_{3} = W_{30}(x) + W_{31}(x) \cos \frac{ny}{R} + W_{32}(x) \cos \frac{2ny}{R} + W_{33}(x) \cos \frac{3ny}{R}$$

$$(39)$$

Paralleling the second perturbation, U_{31} , V_{31} , and W_{31} can be shown to be secular terms which must be eliminated. The resulting algebraic equation in this case can be written as:

$$A_{31}Z_{31} = b\lambda_{cr}c_1D_{31} + c_1^3E_{31}$$
 (40)

where D_{31} is a column vector corresponding to the terms multiplied by b on the right-hand sides of (37) and (38) and E_{31} is a column matrix generated from the terms that are independent of b. In contrast to equation (31), the additional term multiplied by c_1^3 occurs in (40) because, when the general solutions (eqs. (27) and (36)) are substituted into the right-hand sides of (37) and (38), terms such as $\cos ny/R$ $\cos 2ny/R$ result which can be expanded as

$$\cos \frac{ny}{R} \cos \frac{2ny}{R} = \frac{1}{2} \left(\cos \frac{3ny}{R} + \cos \frac{ny}{R}\right)$$

thereby yielding additional secular terms that are independent of b. The condition for removal of the secular terms that is the analogue of equation (34) can be written as

$$Z_{1}^{T}A_{31}Z_{1} = b\lambda_{cr}c_{1}Z_{1}^{T}D_{31} + c_{1}^{3}Z_{1}^{T}E_{31} = 0$$
 (41)

which has the solution

$$b = \frac{-c_1^2 Z_1^T E_{31}}{\lambda_{cr} Z_1^T D_{31}}$$
 (42)

Equation (42) together with consideration of the equilibrium equations and boundary conditions corresponding to the first, second and third perturbations can be shown to imply the following proportionalities:

$$W_1, N_{x_1}, N_{xy_1}, N_{y_1} \propto b^{1/2}$$
 $W_2, N_{x_2}, N_{xy_2}, N_{y_2} \propto b$
 $W_3, N_{x_3}, N_{xy_3}, N_{y_3} \propto b^{3/2}$

It is interesting to note that the counterpart of equation (42) was found by Stein in a study of the postbuckling behavior of plates. (See equation (19) of reference 25.)

The proportionalities indicated in equations (43) have also been found in existing applications of the Koiter theory. For example, Fitch and Cohen in references 23 and 24 have obtained an explicit expression for b from energy considerations. In terms of the present notation, the results of references 23 and 24 can be expressed as:

$$b = -\frac{\int \int \overline{A} \, dx \, dy + 2 \int \int \overline{B} \, dx \, dy}{\sup_{\text{cr}} \int \int \overline{C} \, dx \, dy}$$

$$\lambda_{\text{cr}} \int \int \overline{C} \, dx \, dy$$
(44)

where

$$\overline{A} = N_{x_2} w_{1,x}^2 + N_{y_2} w_{1,y}^2 + 2N_{xy_2} w_{1,x} w_{1,y} + \frac{1}{2} C_{11} w_{1,x}^4 + C_{12} w_{1,x}^2 w_{1,y}^2$$

$$+ \frac{1}{2} C_{22} w_{1,y}^4 + 2C_{66} w_{1,x}^2 w_{1,y}^2$$

$$\overline{\mathbb{B}} = \mathbb{N}_{\mathbb{X}_{\underline{1}}} \ \mathbb{W}_{\underline{1},\mathbb{X}} \ \mathbb{W}_{\underline{2},\mathbb{X}} + \mathbb{N}_{\mathbb{Y}_{\underline{1}}} \ \mathbb{W}_{\underline{1},\mathbb{Y}} \ \mathbb{W}_{\underline{2},\mathbb{Y}} + \mathbb{N}_{\mathbb{X}\mathbb{Y}_{\underline{1}}} (\mathbb{W}_{\underline{1},\mathbb{X}}\mathbb{W}_{\underline{2},\mathbb{Y}} + \mathbb{W}_{\underline{1},\mathbb{Y}} \ \mathbb{W}_{\underline{2},\mathbb{X}})$$

$$\overline{C} = N_{x_0,\lambda}^* w_{1,x}^2 + N_{y_0,\lambda}^* w_{1,y}^2 + 2(N_{x_1} w_{0,x\lambda}^* w_{1,x} + N_{xy_1} w_{0,x\lambda}^* w_{1,y})$$

Using the proportionalities indicated in equation (43), it can be seen that equation (44) becomes independent of b and hence equation (44) must be the counterpart of (42). The general theory of references 23 and 24 can be specialized to a "classical" buckling theory by taking prebuckling deformations consistent with a membrane state of stress. The index b has been obtained under these assumptions by Budiansky in references 20 to 22. For the cylinder, the use of classical buckling theory requires derivatives of w₀ to vanish. Inspection of equation (44) with this assumption reveals again that the equation is independent of b.

Determination of b

To determine b explicitly, the perturbation parameter ξ must be defined appropriately. If the parameter ξ is considered to be a scalar measure of the growth of the displacements in the shell just after buckling, then ξ must be related to the magnitude of these displacements. The displacement vector \overrightarrow{D} is defined to be the following:

$$\overrightarrow{D} = (u - u_0^*)\overrightarrow{i} + v\overrightarrow{j} + (w - w_0^*)\overrightarrow{k}$$
 (45)

so that to the second approximation using (11) with a = 0

$$\overrightarrow{D} = \left[u_1 \xi + (b \lambda_{cr} u_0^*, \lambda + u_2) \xi^2 \right] \overrightarrow{i} + (v_1 \xi + v_2 \xi^2) \overrightarrow{j} + \left[w_1 \xi + (b \lambda_{cr} w_0^*, \lambda + w_2) \xi^2 \right] \overrightarrow{k}$$

$$+ w_2 |\xi^2| \overrightarrow{k}$$

$$(46)$$

The parameter ξ in the present theory is taken to be such that the square of the perturbation parameter is equal to the square of the magnitude of the vector \overrightarrow{D} , $(\overrightarrow{D} \cdot \overrightarrow{D})$, averaged over the cylinder surface and nondimensionalized by the square of the cylinder thickness t. Hence

$$\xi^{2} = \frac{\int \int \overrightarrow{D} \cdot \overrightarrow{D} \, dx \, dy}{2\pi R A t^{2}}$$
 (47)

Using equation (46)

$$2\pi RAt^{2} \xi^{2} = \xi^{2} \int \int \int (u_{1}^{2} + v_{1}^{2} + w_{1}^{2}) dx dy + O(\xi^{3})$$
 (48)

Using the general solution for the first perturbation (eq. (27)) and expressing c_1 in terms of b from equation (42), b can be written as

$$b = \frac{-2\pi RAt^2 Z_1^T E_{31}}{\lambda_{cr} Z_1^T D_{31} \iint_{\text{surface}} \left(U_1^2 \cos^2 \frac{ny}{R} + V_1^2 \sin^2 \frac{ny}{R} + W_1^2 \cos^2 \frac{ny}{R}\right) dx dy}$$
(49)

Thus, to within $0(\xi^2)$, the expression for b becomes

$$b = \frac{-2At^2 Z_1^T E_{31}}{\lambda_{er} Z_1^T D_{31} \int_0^A (U_1^2 + V_1^2 + W_1^2) dx}$$
 (50)

VIII. NUMERICAL SOLUTION OF POSTBUCKLING EQUATIONS

The solution for the state of axisymmetric prestress at buckling has already been presented in closed form (eqs. (18) and (19)). The solution to the equilibrium equations and boundary conditions resulting from the first and second perturbations (eqs. (23), (24), (28), and (29)) were found for simply supported and clamped shells by using numerical methods. Following the finite-difference technique suggested by references 38 and 39, the system of ordinary differential equations resulting from substitution of the general solutions (eqs. (27) and (36)) are cast into a set of simultaneous second-order differential equations and boundary conditions involving the fundamental displacement variables U, V, and W and an auxiliary variable \overline{M}_{x} . By employing central differences, the equations are converted into simultaneous algebraic equations which are then solved on a digital computer by matrix methods. Because the resulting algebraic equations contain banded matrices, it is expedient to employ Gaussian elimination in the solution.

General Solution

In formulating the postbuckling solution, it is convenient to consider the left-hand sides of the equilibrium equations in general. When the general solutions for the first and second perturbations are substituted into the equilibrium equations and the definition of the moment resultant $\overline{\mathbf{M}}_{\mathbf{x}}$ is introduced, the following set of second-order differential equations and boundary conditions are obtained:

$$\Lambda_{11}U'' + \Lambda_{12}U + \Lambda_{13}V' + \Lambda_{14}W'' + \Lambda_{15}W' + \Lambda_{16}W + \Lambda_{17}M' = D_{1}$$

$$\Lambda_{21}U' + \Lambda_{22}V'' + \Lambda_{23}V + \Lambda_{24}W'' + \Lambda_{25}W' + \Lambda_{26}W = D_{2}$$

$$\Lambda_{31}U' + \Lambda_{32}V'' + \Lambda_{33}V + \Lambda_{34}W'' + \Lambda_{35}W' + \Lambda_{36}W - M'' = D_{3}$$

$$\Lambda_{41}U' + \Lambda_{42}V + \Lambda_{43}W'' + \Lambda_{44}W' + \Lambda_{45}W + M = D_{4}$$
(51)

where

$$\begin{split} & \Lambda_{11} = c_{11} - \frac{\kappa_{11}^2}{D_{11}} \\ & \Lambda_{12} = -c_{66} \left(\frac{mn}{R} \right)^2 \\ & \Lambda_{13} = \left(c_{12} + c_{66} - \frac{\kappa_{12} \kappa_{11}}{D_{11}} \right) \frac{mn}{R} \\ & \Lambda_{14} = \left(c_{11} - \frac{\kappa_{11}^2}{D_{11}} \right) w_{0,x}^* \\ & \Lambda_{15} = \left(c_{11} - \frac{\kappa_{11}^2}{D_{11}} \right) w_{0,xx}^* + \left(c_{12} - \frac{\kappa_{12} \kappa_{11}}{D_{11}} \right) \frac{1}{R} + \left(\kappa_{12} + 2\kappa_{66} - \frac{\kappa_{11} D_{12}}{D_{11}} \right) \left(\frac{mn}{R} \right)^2 \\ & \Lambda_{16} = -c_{66} w_{0,x}^* \left(\frac{mn}{R} \right)^2 \\ & \cdot \\ & \Lambda_{17} = \frac{\kappa_{11}}{D_{11}} \end{split}$$

$$\Lambda_{21} = -(c_{12} + c_{66}) \frac{mn}{R}$$

$$\Lambda_{22} = c_{66}$$

$$\Lambda_{23} = -c_{22} \left(\frac{mn}{R}\right)^2$$

$$\Lambda_{24} = (K_{12} + 2K_{66}) \frac{mn}{R}$$

$$\Lambda_{25} = -(c_{12} + c_{66})_{\text{WO,x}}^{*} \frac{\text{mn}}{R}$$

$$\Lambda_{26} = -c_{66} w_{0,xx}^{*} \frac{mn}{R} - \frac{c_{22}mn}{R^{2}} - \kappa_{22} \left(\frac{mn}{R}\right)^{3}$$

$$\Lambda_{31} = \frac{c_{12}}{R} + (\kappa_{12} + 2\kappa_{66}) \left(\frac{mn}{R}\right)^2 - c_{11} w_{0,xx}^*$$

$$\Lambda_{32} = -2K_{66} \frac{mn}{R}$$

$$\Lambda_{33} = \frac{c_{22}mn}{R^2} + K_{22} \left(\frac{mn}{R}\right)^3 - c_{12} w_{0,xx}^* \frac{mn}{R}$$

$$\Lambda_{\rm 34} \, = \, \lambda_{\rm cr} \, - \, \frac{\kappa_{\rm 12}}{\rm R} \, - \, (4 D_{\rm 66} \, + \, D_{\rm 12}) \left(\frac{\rm mn}{\rm R} \right)^2 \, + \, \kappa_{\rm 11} w_{\rm 0,xx}^{\star}$$

$$\Lambda_{35} = \left[\frac{c_{12}}{R} + (\kappa_{12} + 2\kappa_{66}) \left(\frac{mn}{R}\right)^{2}\right] w_{0,x}^{*} - c_{11} w_{0,x}^{*} w_{0,xx}^{*}$$

$$\Lambda_{36} = \left\{ \left[\frac{C_{12}K_{11}}{C_{11}} + 2(K_{66} - K_{12}) \right] \left(\frac{mn}{R} \right)^2 - \frac{C_{12}}{R} \right\} w_0^*,_{xx} + \frac{1}{R} \left(C_{22} - \frac{C_{12}^2}{R} \right) \left(\frac{mn}{R} \right)^2 w_0^*$$

$$+ D_{22} \left(\frac{mn}{R} \right)^{1/4} + \frac{2K_{22}}{R} \left(\frac{mn}{R} \right)^2 + \frac{C_{22}}{R^2} - \frac{C_{12}^2}{C_{11}} \left(\frac{mn}{R} \right)^2 \lambda_{cr}$$

$$\Lambda_{41} = -K_{11}$$

$$\Lambda_{42} = -K_{12} \frac{mn}{R}$$

$$\Lambda_{43} = D_{11}$$

$$\Lambda_{\underline{1}\underline{1}\underline{1}} = -K_{\underline{1}\underline{1}}w_{0,x}^{*}$$

$$\Lambda_{45} = -\left[D_{12}\left(\frac{mn}{R}\right)^2 + \frac{K_{12}}{R}\right]$$

with

$$m = 0$$
 \longrightarrow U_{20} , V_{20} , W_{20} , M_{20}
 $m = 1$ \longrightarrow U_{1} , V_{1} , W_{1} , M_{1}
 $m = 2$ \longrightarrow U_{22} , V_{22} , W_{22} , M_{22}

and D_i (i = 1 to 4) the corresponding loading terms.

If the central difference formulae

$$f_{i}^{"} = \frac{f_{i+1} - f_{i-1}}{2\Delta}$$

$$f_{i}^{"} = \frac{f_{i+1} - 2f_{i} + f_{i-1}}{\Delta^{2}}$$
(52)

are employed, equations (51) can be written at the ith station as

$$A_{i}Z_{i-1} + B_{i}Z_{i} + C_{i}Z_{i+1} = D_{i}$$
 (i = 1,2,...,N) (53)

with

$$A_{1} = \begin{bmatrix} \Lambda_{11} & -\frac{\Delta}{2}\Lambda_{13} & \Lambda_{14} - \frac{\Delta}{2}\Lambda_{15} & -\frac{\Delta}{2}\Lambda_{17} \\ -\frac{\Delta}{2}\Lambda_{21} & \Lambda_{22} & \Lambda_{24} - \frac{\Delta}{2}\Lambda_{25} & 0 \\ -\frac{\Delta}{2}\Lambda_{31} & \Lambda_{32} & \Lambda_{34} - \frac{\Delta}{2}\Lambda_{35} & -1 \\ -\frac{\Delta}{2}\Lambda_{41} & 0 & \Lambda_{43} - \frac{\Delta}{2}\Lambda_{44} & 0 \end{bmatrix}$$

$$B_{1} = \begin{bmatrix} -2\Lambda_{11} + \Delta^{2}\Lambda_{12} & 0 & -2\Lambda_{14} + \Delta^{2}\Lambda_{16} & 0 \\ 0 & -2\Lambda_{22} + \Delta^{2}\Lambda_{23} & -2\Lambda_{24} + \Delta^{2}\Lambda_{26} & 0 \\ 0 & -2\Lambda_{32} + \Delta^{2}\Lambda_{33} & -2\Lambda_{34} + \Delta^{2}\Lambda_{36} & 2 \\ 0 & \Delta^{2}\Lambda_{42} & -2\Lambda_{43} + \Delta^{2}\Lambda_{45} & \Delta^{2} \end{bmatrix}$$

$$c_{1} = \begin{bmatrix} \Lambda_{11} & \frac{\Delta}{2} \Lambda_{13} & \Lambda_{14} + \frac{\Delta}{2} \Lambda_{15} & \frac{\Delta}{2} \Lambda_{17} \\ \frac{\Delta}{2} \Lambda_{21} & \Lambda_{22} & \Lambda_{24} + \frac{\Delta}{2} \Lambda_{25} & 0 \\ \frac{\Delta}{2} \Lambda_{31} & \Lambda_{32} & \Lambda_{34} + \frac{\Delta}{2} \Lambda_{35} & -1 \\ \frac{\Delta}{2} \Lambda_{41} & 0 & \Lambda_{43} + \frac{\Delta}{2} \Lambda_{44} & 0 \end{bmatrix}$$

where Δ is the width of a finite-difference space and i is numbered so that i = 1, N corresponds to the boundaries of the cylinder.

Boundary Conditions

For the present investigation, the so-called "classical" simple support and clamped boundary conditions were employed, that is, for simple support

$$\begin{bmatrix}
N_{\mathbf{X}} = -\lambda \\
\mathbf{y} = 0 \\
W = 0 \\
M_{\mathbf{X}} = 0
\end{bmatrix}$$
(54)

at the boundaries, while for clamped support

$$\begin{bmatrix}
 N_{\mathbf{X}} = -\lambda \\
 v = 0 \\
 w = 0 \\
 w_{\mathbf{X}} = 0
 \end{bmatrix}$$
(55)

at the boundaries.

Using the results of the first and second perturbations (eqs. (27) and (36)) and the finite-difference approximations, the boundary conditions can be written as

$$\overline{A}_{1}Z_{0} + \overline{B}_{1}Z_{1} + \overline{C}_{1}Z_{2} = \overline{D}_{1}$$

$$\overline{A}_{N}Z_{N-1} + \overline{B}_{N}Z_{N} + \overline{C}_{N}Z_{N+1} = \overline{D}_{N}$$
(56)

where for simple support

$$\overline{A}_{1} = \begin{bmatrix} -c_{11} \frac{\Delta}{2} & 0 & -K_{11} - c_{11} w_{0,x}^{*}(1) \frac{\Delta}{2} & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\overline{B}_{1} = \begin{bmatrix} 0 & \frac{mn}{R} c_{12} \Delta^{2} & \frac{c_{12}}{R} \Delta^{2} + 2K_{11} + K_{12} \Delta^{2} \left(\frac{mn}{R}\right)^{2} & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

and \overline{A}_N , \overline{B}_N , and \overline{C}_N are given by similar expressions differing only in that $w_{O,x}^*$ is evaluated at station N rather than station 1.

For clamped support, the last row of equations (56) is modified so that

$$\overline{A}_{1}(4,j) = \begin{bmatrix} 0 & 0 & -\frac{\Delta}{2} & 0 \end{bmatrix} = \overline{A}_{N}(4,j)$$

$$\overline{B}_{1}(4,j) = \begin{bmatrix} 0 & 0 & 0 & 0 \end{bmatrix} = \overline{B}_{N}(4,j)$$

$$\overline{C}_{1}(4,j) = \begin{bmatrix} 0 & 0 & \frac{\Delta}{2} & 0 \end{bmatrix} = \overline{C}_{N}(4,j)$$
(57)

The contribution by points exterior to the boundary (denoted by the subscripts 0 and N+1) introduced by the finite-difference scheme is eliminated by writing the equilibrium equation at the boundary (see, for example, ref. 38), thereby obtaining two simultaneous equations in three unknowns at each boundary. If the exterior points are algebraically eliminated, the equilibrium equations and boundary conditions take the following form:

and

$$\overline{Z}_{11}(i) = \begin{bmatrix} \overline{U}_1(i) \\ \overline{V}_1(i) \\ \overline{W}_1(i) \end{bmatrix} \text{ where } i \text{ denotes the ith station } i = (1, 2, ..., N)$$

Since A_{ll} is a banded matrix, it is convenient to triangularize A_{ll} by Gaussian elimination so that equation (59) becomes

$$\hat{A}_{11}\overline{Z}_{11} = 0 \tag{60}$$

where

$$\hat{A}_{11} = \begin{bmatrix} R_1 & C_1 & & & & & \\ & R_2 & C_2 & & & & \\ & \ddots & \ddots & \ddots & & & \\ & & & R_{N-1} & C_{N-1} & & \\ & & & & R_N & & \end{bmatrix}$$
(61)

and

$$R_1 = \hat{B}_1$$

$$R_{i} = B_{i} - A_{i}P_{i-1}$$
 $i = 2,3,...,N$

with

$$P_1 = \hat{B}_1^{-1}\hat{C}_1$$

$$P_1 = \hat{R}_1^{-1}C_1 \qquad i = 2,3,...,N$$

where

$$\hat{B}_{1} = \overline{B}_{1} - \overline{A}_{1}A_{1}^{-1}B_{1}$$

$$\hat{C}_{1} = \overline{C}_{1} - \overline{A}_{1}A_{1}^{-1}C_{1}$$

$$\hat{D}_{1} = \overline{D}_{1} - \overline{A}_{1}A_{1}^{-1}D_{1}$$

$$\hat{A}_{N} = \overline{A}_{N} - \overline{C}_{N}C_{N}^{-1}A_{N}$$

$$\hat{B}_{N} = \overline{B}_{N} - \overline{C}_{N}C_{N}^{-1}B_{N}$$

$$\hat{D}_{N} = \overline{D}_{N} - \overline{C}_{N}C_{N}^{-1}D_{N}$$

Solutions to equations (58) for each of the perturbations are discussed in the following sections.

Solution for First Perturbation

For the first perturbation, the right-hand side of equation (58) becomes a null vector so that the equation becomes

$$A_{11}\overline{Z}_{11} = 0 \tag{59}$$

where

$$A_{11} = \begin{bmatrix} \hat{B}_{1} & \hat{C}_{1} \\ A_{2} & B_{2} & C_{2} \\ & A_{3} & B_{3} & C_{3} \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ &$$

A condition for solution of equation (60) is that

$$\det \hat{A}_{11} = 0$$

so that

$$\det(R_1R_2...R_N) = 0$$

Using Potters' method (ref. 42) applied to a general eigenvalue problem, it can be shown that det $R_{\rm N}=0$ is a sufficient condition for solution. This determinant, however, contains spurious poles which can be removed conveniently by the method outlined in reference 40 using the condition

$$\frac{\det R_1}{\left|\det R_1\right|} \frac{\det R_2}{\left|\det R_2\right|} \dots \det R_N = 0 \tag{62}$$

For the first perturbation solution, $\lambda_{\rm cr}$ must be such that equation (62) is satisfied. For the present study, the buckling load was determined from a computer program developed in reference 41 by using the techniques of reference 38, and equation (62) was used to verify the accuracy of the present equations. The buckling solution of reference 41 differs from the present solution for the zeroth and first perturbation only in that deformations prior to buckling are found from a numerical rather than closed-form solution, and that provision is made to investigate various values of n and the applied load in order to find the buckling load $\lambda_{\rm cr}$ by determinant plotting (see also ref. 38). Once the buckling load has been determined, its corresponding eigenvector can be found by a method suggested by reference 38.

If

$$R_{\text{N}} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix}$$

it can be shown that the components of the eigenvector at the boundary are given by

$$\overline{U}_{1}(N) = \det \begin{bmatrix} a_{12} & a_{13} & a_{14} \\ a_{22} & a_{23} & a_{24} \\ a_{42} & a_{43} & a_{44} \end{bmatrix}$$

$$\overline{V}_{1}(N) = -\det \begin{bmatrix} a_{11} & a_{13} & a_{14} \\ a_{21} & a_{23} & a_{24} \\ a_{41} & a_{43} & a_{44} \end{bmatrix}$$

$$\overline{W}_{1}(N) = \det \begin{bmatrix} a_{11} & a_{12} & a_{14} \\ a_{21} & a_{22} & a_{24} \\ a_{41} & a_{42} & a_{44} \end{bmatrix}$$

$$\overline{M}_{1}(N) = -\det \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{41} & a_{42} & a_{43} \end{bmatrix}$$

$$\overline{M}_{1}(N) = -\det \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{41} & a_{42} & a_{43} \end{bmatrix}$$

With the components of the vector $\overline{Z}_{11}(N)$ known, the eigenvectors at other stations are found from the recurrence relation

$$\overline{Z}_{11}(i) = -P_i \overline{Z}_{11}(i+1)$$
 $i = 1, 2, ..., N-1$ (64)

After obtaining \overline{z}_{11} at all stations, the resulting vector was normalized for the present computations so that

$$z_{11} = \frac{\overline{z}_{11}}{\left|\frac{\overline{w}_{1}(i)_{\text{max}}}{t}\right|}$$
 (65)

with

$$Z_{11}(i) = \begin{cases} U_{1}(i) \\ V_{1}(i) \\ W_{1}(i) \\ M_{1}(i) \end{cases} \qquad i = 1, 2, ..., N$$

This normalization was used as a convenience to compare results from conventional Koiter theory (e.g., eq. (44)) with the present theory.

Solution for Second Perturbation

For the second perturbation, the equilibrium equations can be written as

$$A_{2m}Z_{2m} = D_{2m}$$
 $m = 0,2$ (66)

with

$$A_{2m} = \begin{bmatrix} \hat{B}_{1} & \hat{C}_{1} \\ A_{2} & B_{2} & C_{2} \\ & A_{3} & B_{3} & C_{3} \\ & & & A_{N-2} & B_{N-2} & C_{N-2} \\ & & & & A_{N-1} & B_{N-1} & C_{N-1} \\ & & & & \hat{A}_{N} & \hat{B}_{N} \end{bmatrix}$$

$$Z_{2m}(i) = \begin{bmatrix} U_{2m}(i) \\ V_{2m}(i) \\ W_{2m}(i) \\ W_{2m}(i) \end{bmatrix} \quad \text{and} \quad D_{2m}(i) = \Delta^{2} \begin{bmatrix} d_{21}(i) \\ d_{22}(i) \\ d_{23}(i) \\ d_{24}(i) \end{bmatrix}$$

where m takes on the value 0 to evaluate the axisymmetric part of the general solution (eq. (36)), for example, W_{20} , and m has the value 2 for the asymmetric part, for example, W_{22} . In equation (66), the components of the vector D_{2m} can be written at the ith station as

$$\begin{aligned} \mathbf{d}_{21}(\mathbf{i}) &= -\frac{1}{2} \, \mathbf{C}_{11} \mathbf{W}_{1}^{i} \mathbf{W}_{1}^{i} + \frac{\mathbf{m} - 1}{2} \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \, \mathbf{C}_{12} \mathbf{W}_{1} \mathbf{W}_{1}^{i} + \frac{\mathbf{m}}{2} \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \, \mathbf{C}_{66} \mathbf{W}_{1} \mathbf{W}_{1}^{i} \\ \mathbf{d}_{22}(\mathbf{i}) &= \frac{\mathbf{m}}{2} \left[\mathbf{n} (\mathbf{c}_{12} + \mathbf{c}_{66}) (\mathbf{W}_{1}^{i})^{2} - \frac{1}{2} \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{3} \, \mathbf{c}_{22} \mathbf{W}_{1}^{2} + \frac{\mathbf{n}}{2\mathbf{R}} \, \mathbf{c}_{66} \mathbf{W}_{1} \mathbf{W}_{1}^{ii} \right] \\ \mathbf{d}_{23}(\mathbf{i}) &= \frac{\mathbf{K}_{11}}{2} \left[(\mathbf{W}_{1}^{i})^{2} + \mathbf{W}_{1}^{i} \mathbf{W}_{1}^{i} \right] - \left(\frac{\mathbf{m} - 1}{2} \, \mathbf{K}_{12} + \mathbf{m} \mathbf{K}_{66} \right) \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \, \mathbf{W}_{1} \mathbf{W}_{1}^{ii} \\ &+ \left(\frac{1 - 2\mathbf{m}}{2} \, \mathbf{K}_{12} - \mathbf{m} \mathbf{K}_{66} \right) \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} + \frac{1}{4} \left(\mathbf{c}_{11} \mathbf{w}_{0}^{*}, \mathbf{x} \mathbf{x} - \frac{\mathbf{c}_{12}}{\mathbf{R}} \right) \right] (\mathbf{W}_{1}^{i})^{2} \\ &+ \left(\frac{\mathbf{m}}{2} \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \, \mathbf{K}_{22} + \frac{\mathbf{m} - 1}{4} \left(\frac{\mathbf{c}_{22}}{\mathbf{R}} - \mathbf{c}_{12} \mathbf{w}_{0}^{*}, \mathbf{x} \mathbf{x} \right) \right) \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \, \mathbf{W}_{1}^{2} \\ &+ \frac{1}{2} \, \overline{\mathbf{N}}_{\mathbf{x}_{1}} \mathbf{W}_{1}^{ii} + (\mathbf{m} - 1) \, \frac{\mathbf{n}}{\mathbf{R}} \, \overline{\mathbf{N}}_{\mathbf{x}_{2}} \mathbf{W}_{1}^{i} - \frac{1}{2} \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \, \overline{\mathbf{N}}_{\mathbf{y}_{1}} \mathbf{W}_{1} \end{aligned}$$

where the bar over the stress resultants indicates the part of the stress resultant that is independent of y (viz., $N_{x_1} = \overline{N}_{x_1} \cos \frac{ny}{R}$).

Following the development used to eliminate exterior points in the general solution (see section entitled :Boundary Conditions)

$$\hat{\mathbf{D}}_{2m}(\mathbf{1}) = \overline{\mathbf{D}}_{2m}(\mathbf{1}) - \overline{\mathbf{A}}_{1}\mathbf{A}_{1}^{-1}\mathbf{D}_{2m}(\mathbf{1})$$

$$\hat{\mathbf{D}}_{2m}(\mathbf{N}) = \overline{\mathbf{D}}_{2m}(\mathbf{N}) - \overline{\mathbf{C}}_{N}\mathbf{C}_{N}^{-1}\mathbf{D}_{2m}(\mathbf{N})$$
(68)

where \overline{A}_1 , A_1 , \overline{C}_1 , and C_1 are evaluated for m=0 or m=2. For simple support boundary conditions

$$\overline{D}_{2m} = -\Delta^{2} \begin{cases} \frac{1}{4} C_{11} [W_{1}^{t}(i)]^{2} \\ 0 \\ 0 \\ \frac{1}{4} K_{11} [W_{1}^{t}(i)]^{2} \end{cases} \qquad i = 1, N$$
 (69)

and for clamped boundary conditions, \overline{D}_{2m} becomes a null vector. It should also be noted that rigid body displacements will occur in U_{20} if $N_{x_{20}}$ is prescribed at both ends of the cylinder. To suppress these deformations, the boundary conditions of equations (68) and (69) were modified so that the axial displacement was fixed at one end (i.e., $U_{20}(N) = 0$).

Thus, the solution for displacements resulting from the second perturbation requires solutions to two sets of simultaneous algebraic equations having the form

$$\begin{bmatrix} \hat{B}_{1} & \hat{C}_{1} \\ A_{2} & B_{2} & C_{2} \\ A_{3} & B_{3} & C_{5} \\ \vdots & \vdots & \vdots & \vdots \\ A_{N-2} & B_{N-2} & C_{N-2} \\ A_{N} & \hat{B}_{N} & \hat{B}_{N} \end{bmatrix} \begin{bmatrix} Z_{2m}(1) \\ Z_{2m}(2) \\ Z_{2m}(3) \\ \vdots & \vdots & \vdots \\ Z_{2m}(N-2) \\ Z_{2m}(N-2) \\ Z_{2m}(N-1) \\ Z_{2m}(N) \end{bmatrix} = \begin{bmatrix} \hat{D}_{2m}(1) \\ D_{2m}(2) \\ D_{2m}(3) \\ \vdots & \vdots \\ D_{2m}(N-2) \\ D_{2m}(N-1) \\ \hat{D}_{2m}(N) \end{bmatrix}$$
with $m = 0, 2$.

To solve these equations, Gaussian elimination (sometimes referred to as Potters' method, ref. 42) was employed on a digital computer.

Evaluation of b

As mentioned in the derivation of the governing equations, the determination of b requires identification of the secular terms occurring in the general solution of the third perturbation. To accomplish this, the general solutions of equations (39) are substituted into the equilibrium equations, and terms whose coefficients are either $\cos \frac{ny}{R}$ or $\sin \frac{ny}{R}$ are collected. The resulting equilibrium equations associated only with secular terms can be written as

$$A_{11}Z_{31} = b\lambda_{cr}c_{1}D_{31} + c_{1}Z_{31}$$
 (71)

in which

$$D_{31} = \Delta^{2} \begin{bmatrix} d_{31}(i) \\ d_{32}(i) \\ d_{33}(i) \\ 0 \end{bmatrix} \qquad i = 1, 2, ..., N$$

with

$$\begin{split} \mathbf{d}_{31}(\mathbf{i}) &= -\mathbf{c}_{11}(\mathbf{w}_{0}^{*}, \mathbf{x}\lambda \mathbf{w}_{1}^{n} + \mathbf{w}_{0}^{*}, \mathbf{x}x\lambda \mathbf{w}_{1}^{n}) + \left(\frac{n}{R}\right)^{2} \mathbf{c}_{66}\mathbf{w}_{0}^{*}, \mathbf{x}\lambda \mathbf{w}_{1} \\ \mathbf{d}_{32}(\mathbf{i}) &= \frac{n}{R} \mathbf{c}_{66}\mathbf{w}_{0}^{*}, \mathbf{x}x\lambda \mathbf{w}_{1} + \frac{n}{R}(\mathbf{c}_{12} + \mathbf{c}_{66})\mathbf{w}_{0}^{*}, \mathbf{x}\lambda \mathbf{w}_{1}^{n} \\ \mathbf{d}_{33}(\mathbf{i}) &= -\mathbf{w}_{1}^{n} + \overline{\mathbf{N}}_{\mathbf{x}_{1}}\mathbf{w}_{0}^{*}, \mathbf{x}x\lambda - \left(\frac{n}{R}\right)^{2} \mathbf{N}_{\mathbf{y}_{0},\lambda}^{*}\mathbf{w}_{1} \\ &+ \mathbf{c}_{11}\mathbf{w}_{0}^{*}, \mathbf{x}x\mathbf{w}_{0}^{*}, \mathbf{x}\lambda \mathbf{w}_{1}^{n} - \frac{\mathbf{c}_{12}}{R} \mathbf{w}_{0}^{*}, \mathbf{x}\lambda \mathbf{w}_{1}^{n} \\ &+ \mathbf{K}_{11}(\mathbf{w}_{0}^{*}, \mathbf{x}\lambda \mathbf{w}_{1}^{n} + 2\mathbf{w}_{0}^{*}, \mathbf{x}x\lambda \mathbf{w}_{1}^{n} + \mathbf{w}_{0}^{*}, \mathbf{x}xx\lambda \mathbf{w}_{1}^{n}) \\ &- 2\left(\frac{n}{R}\right)^{2} \mathbf{K}_{66}\mathbf{w}_{0}^{*}, \mathbf{x}x\lambda \mathbf{w}_{1} - \left(\frac{n}{R}\right)^{2}(2\mathbf{K}_{66} + \mathbf{K}_{12})\mathbf{w}_{0}^{*}, \mathbf{x}\lambda \mathbf{w}_{1}^{n} \end{split}$$

and

$$\dot{E}_{31} = \Delta^{2} \begin{bmatrix} e_{31}(i) \\ e_{32}(i) \\ e_{33}(i) \end{bmatrix} \qquad i = 1, 2, ..., N$$

with

$$\begin{split} \mathbf{e}_{31}(\mathbf{i}) &= -\mathbf{c}_{11} \left[\mathbf{W}_{1}^{"} \left(\mathbf{W}_{20}^{"} + \frac{1}{2} \; \mathbf{W}_{22}^{"} \right) + \; \mathbf{W}_{1}^{"} \left(\mathbf{W}_{20}^{"} + \frac{1}{2} \; \mathbf{W}_{22}^{"} \right) \right] \\ &+ \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \; \mathbf{c}_{12} \left(\mathbf{W}_{1}^{"} \mathbf{W}_{22} + \; \mathbf{W}_{1} \mathbf{W}_{22}^{"} \right) \\ &+ \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^{2} \; \mathbf{c}_{66} \left(3 \mathbf{W}_{1}^{"} \mathbf{W}_{22} + \frac{3}{2} \; \mathbf{W}_{1} \mathbf{W}_{22}^{"} + \; \mathbf{W}_{1} \mathbf{W}_{20}^{"} \right) \end{split}$$

$$\begin{split} \mathbf{e}_{32}(\mathbf{i}) &= \frac{\mathbf{n}}{\mathbf{R}} (\mathbf{c}_{12} + \mathbf{c}_{66}) \mathbf{W}_{1}^{\mathbf{i}} \Big(\mathbf{W}_{20}^{\mathbf{i}} + \frac{1}{2} \mathbf{W}_{22}^{\mathbf{i}} \Big) \\ &+ \frac{\mathbf{n}}{\mathbf{R}} \mathbf{c}_{66} \Big[\mathbf{W}_{1}^{\mathbf{i}} \mathbf{W}_{22} + \mathbf{W}_{1} \Big(\mathbf{W}_{20}^{\mathbf{i}} - \frac{1}{2} \mathbf{W}_{22}^{\mathbf{i}} \Big) \Big] \\ &+ \Big(\frac{\mathbf{n}}{\mathbf{R}} \Big)^{3} \mathbf{c}_{22} \mathbf{W}_{1} \mathbf{W}_{22} \end{split}$$

$$\begin{split} & = \mathbf{E}_{33}(\mathbf{i}) = \overline{\mathbf{K}}_{33} + \overline{\mathbf{C}}_{33} + \mathbf{w}_{0,xx}^* \left[\mathbf{C}_{11} \mathbf{w}_{1}^* \left(\mathbf{w}_{20}^* + \frac{1}{2} \mathbf{w}_{22}^* \right) - \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^2 \mathbf{C}_{12} \mathbf{w}_{1} \mathbf{w}_{22} \right] \\ & + \overline{\mathbf{N}}_{x_1} \left(\mathbf{w}_{20}^* + \frac{1}{2} \mathbf{w}_{22}^* \right) + \left(\overline{\mathbf{N}}_{x_{20}} + \frac{1}{2} \overline{\mathbf{N}}_{x_{22}} \right) \mathbf{w}_{1}^* \\ & - 2 \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^2 \overline{\mathbf{N}}_{y_1} \mathbf{w}_{22} - \left(\frac{\mathbf{n}}{\mathbf{R}} \right)^2 \mathbf{w}_{1} \left(\overline{\mathbf{N}}_{y_{20}} + \frac{1}{2} \overline{\mathbf{N}}_{y_{22}} \right) \\ & + 2 \frac{\mathbf{n}}{\mathbf{R}} \overline{\mathbf{N}}_{xy_1} \mathbf{w}_{22}^* + \frac{\mathbf{n}}{\mathbf{R}} \overline{\mathbf{N}}_{xy_{22}} \mathbf{w}_{1}^* \end{split}$$

where

$$\begin{split} \overline{K}_{33} &= K_{11} \left[\overline{W}_{1}^{1''} \left(W_{20}^{1} + \frac{1}{2} W_{22}^{1} \right) + W_{1}^{"} (2W_{20}^{"} + W_{22}^{"}) + W_{1}^{1} \left(W_{20}^{1''} + \frac{1}{2} W_{22}^{1'} \right) \right] \\ &- \left(\frac{n}{R} \right)^{2} K_{12} \left[\overline{W}_{1}^{"} W_{22} + W_{1}^{1} \left(W_{20}^{1} + \frac{13}{2} W_{22}^{1} \right) + W_{1} W_{22}^{"} \right] + 9 \left(\frac{n}{R} \right)^{3} K_{22} W_{1} W_{22} \\ &- \left(\frac{n}{R} \right)^{2} K_{66} \left[6W_{1}^{"} W_{22} + W_{1}^{1} \left(2W_{20}^{1} + 9W_{22}^{1} \right) + W_{1} \left(2W_{20}^{"} + 3W_{22}^{"} \right) \right] \\ &- \overline{C}_{33} = \frac{1}{R} \left[\left(\frac{n}{R} \right)^{2} C_{22} W_{1} W_{22} - C_{12} W_{1}^{1} \left(W_{20}^{1} + \frac{1}{2} W_{22}^{1} \right) \right] \\ &+ W_{1}^{"} \left[\frac{3}{8} C_{11} \left(W_{1}^{1} \right)^{2} + \frac{1}{8} \left(\frac{n}{R} \right)^{2} C_{12} W_{1}^{2} \right] \\ &- \left(\frac{n}{R} \right)^{2} W_{1} \left[\frac{3}{8} C_{12} \left(W_{1}^{1} \right)^{2} + \frac{1}{8} \left(\frac{n}{R} \right)^{2} C_{22} W_{1}^{2} \right] \\ &+ \frac{1}{2} \left(\frac{n}{R} \right)^{2} C_{66} \left(W_{1}^{1} \right)^{2} W_{1} \end{split}$$

Following the procedure for development of boundary conditions

$$\hat{D}_{31}(1) = \overline{D}_{31}(1) - \overline{A}_{1}A_{1}^{-1}D_{31}(1)$$

$$\hat{D}_{31}(N) = \overline{D}_{31}(N) - \overline{C}_{1}C_{1}^{-1}D_{31}(N)$$
(72a)

and

$$\hat{E}_{31}(1) = \overline{E}_{31}(1) - \overline{A}_{1}A_{1}^{-1}E_{31}(1)$$

$$\hat{E}_{31}(N) = \overline{E}_{31}(N) - \overline{C}_{1}C_{1}^{-1}E_{31}(N)$$
(72b)

where \overline{A}_1 , A_1 , \overline{C}_1 , and C_1 are evaluated for m = 1.

For simple support boundary conditions

$$\vec{D}_{31}(i) = -\Delta^{2} \begin{bmatrix} C_{11}w_{0,x\lambda}^{*}(i)w_{1}^{*}(i) \\ 0 \\ 0 \\ K_{11}w_{0,x\lambda}^{*}(i)w_{1}^{*}(i) \end{bmatrix} \qquad i = 1,N$$
(73a)

$$\overline{E}_{31}(i) = -\Delta^{2} \begin{bmatrix} c_{11}W_{1}'(i) \left[W_{20}'(i) + \frac{1}{2}W_{22}'(i)\right] \\ 0 \\ 0 \\ K_{11}W_{1}'(i) \left[W_{20}'(i) + \frac{1}{2}W_{22}'(i)\right] \end{bmatrix} \qquad (73b)$$

For clamped boundary conditions, \overline{D}_{31} and \overline{E}_{31} become null vectors. Thus the vectors D_{31} and E_{31} can be written as

$$D_{31} = \begin{bmatrix} \hat{D}_{31}(1) \\ D_{31}(2) \\ \vdots \\ D_{31}(N-1) \\ \hat{D}_{31}(N) \end{bmatrix} \quad \text{and} \quad E_{31} = \begin{bmatrix} \hat{E}_{31}(1) \\ E_{31}(2) \\ \vdots \\ E_{31}(N-1) \\ \hat{E}_{31}(N) \end{bmatrix}$$

$$(74)$$

Finally, using the equation for b (eq. (50)) previously developed

$$b = \frac{-2t^2 A Z_{11}^T E_{31}}{\lambda_{cr} Z_{11}^T D_{31} \int_0^A (U_1^2 + V_1^2 + W_1^2) dx}$$
(75)

Program SICK

The numerical computations to determine the sensitivity index b were performed on a CDC 6600 series computer using a Fortran program entitled SICK (Sensitivity Index for Cylinders ex Koiter). A listing of this program is contained in appendix A. In the program, four key subroutines were employed: MATRIX, PØTTER, DIF, and SIMP. MATRIX is a CDC general purpose program which permits addition, subtraction, multiplication and inversion of matrices. PØTTER is a Langley Research Center program which solves banded matrix equations with a three-vector bandwidth by Gaussian elimination (Potters' method, ref. 42). DIF is a Langley program which numerically differentiates a function using a 10-point Gauss quadrature method. SIMP is an elementary program which integrates a function by Simpson's rule.

The numerical results were found to converge with about 40 finite-difference elements. The results presented herein were obtained with 60 elements. In the numerical approach employed, a major consideration was computer storage required to solve, the equations resulting from the second perturbation (eqs. (70)) using the subroutine PØTTER. The choice of 60 elements was largely dictated by the fact that it led to a requirement of 70,000 octal storage units by program SICK. This storage was the

maximum obtainable on the Langley remote terminal system. Running times for a typical problem were quite excellent with the solution requiring about 25 seconds' computing time.

•

IX. INVESTIGATION OF RELATIVE IMPERFECTION SENSITIVITY OF FIBER-REINFORCED CYLINDERS

The imperfection sensitivity of certain fiber-reinforced cylinders was investigated with the Koiter index b determined from both the present theory (eq. (75)) as well as the theory of references 23 and 24. To employ the latter theory, equation (44) was employed together with the normalization described in equation (65). Three types of cylinders were considered: glass-epoxy, boron-epoxy, and aluminum reinforced with an overlay of boron-epoxy. The cylinders considered had a fixed radius-thickness ratio R/t of 100 and a length-radius ratio A/R of 0.7. The helical wrap angle of the cylinders was varied in an attempt to identify configurations of minimum imperfection sensitivity.

The investigation of the sensitivity index was limited to a few specific configurations because of the tedious and expensive nature of the calculations. It was found that buckling loads using the theory of reference 41 could be extracted by computer with only moderate difficulty. However, many additional computations were required in certain instances to obtain a buckling mode shape sufficiently accurate to pursue postbuckling calculations.

The elastic constants for the single fiber-reinforced layer in each cylinder were estimated by the procedure summarized in an appendix of reference 1. In this procedure elastic constants along principal axes of unidirectionally reinforced material were obtained from the theoretical study by Hashin and Rosen (ref. 33). The upper bound of the random fiber array model described therein was employed in the present study.

Elastic constants for the helically wrapped layers with filaments oriented at ±a from the cylinder axis were estimated using transformation equations of orthotropic elasticity together with the concept of effective stiffness of cross-plied laminates (refs. 35, 36). This technique has been shown to give predictions in reasonable agreement with experiments to determine elastic constants of glass-epoxy (ref. 1) or boron-epoxy (ref. 4) cylinders. Constituent material properties and layer properties are summarized in table I.

Glass-Epoxy Cylinders

The cylinders investigated were composed of a single helically wrapped layer ($\pm \alpha$). The constituent properties and fiber volume fraction v_f selected for the investigation are typical of well-made filament-wound cylinders. Buckling predictions for cylinders whose wrap angle varies from 0 to 90° are shown in figure 3. The predictions are based on boundary conditions of simple support in which

$$N_{XJ} = 0$$
 $v_{L} = 0$
 $w_{L} = 0$
 $M_{XJ} = 0$

The solid curves of figure 3 labeled "consistent theory" were obtained from reference 41 from a theory which considers nonlinear effects of change in shape of the cylinder due to load prior to buckling. The dash-dot curves of figure 3 labeled "classical theory" were obtained from the theory of reference 2 which assumes a membrane state of stress in the

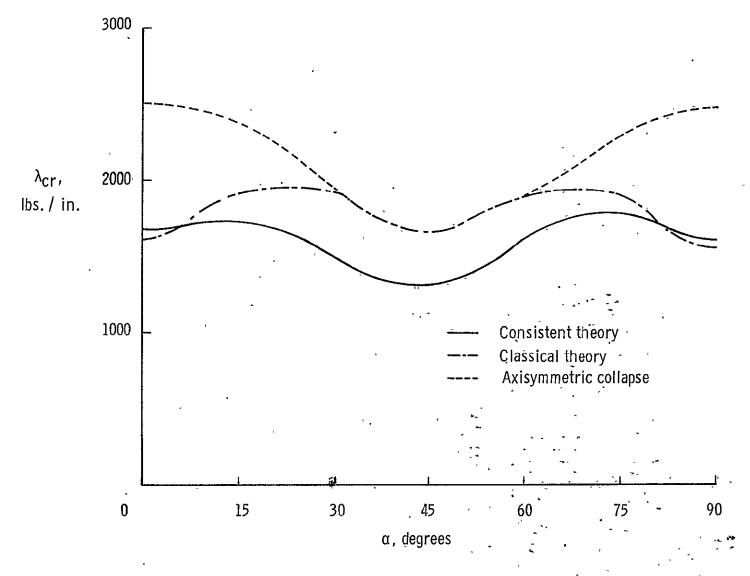

Figure 3.- Buckling loads for glass-epoxy cylinders (R/t = 100, A/R = 0.7, $v_f = 0.65$).

cylinder prior to buckling and ignores changes in shape due to loading. The dashed curve labeled "axi-symmetric collapse" can be obtained from either classical theory with n equal to zero (ref. 2) or by a limiting solution of equations governing axi-symmetric deformations prior to buckling (e.g., eq. (17)).

From figure 3 it can be seen that on the basis of classical theory, cylinders with helical wrap angles from 30 to 60° are expected to collapse axisymmetrically. Consistent theory predictions, however, do not suggest this mode, but rather gives loads based on asymmetric modes which are substantially lower than axisymmetric collapse predictions. The relative position of axisymmetric collapse predictions to consistent theory buckling predictions is extremely important in the present considerations of imperfection sensitivity, because the sensitivity index b is undefined when axisymmetric collapse is the predicted mode of failure. Thus, because consistent theory predictions are less than axisymmetric collapse predictions for all values of the helical wrap angle, the sensitivity index can be defined everywhere.

Substantial differences between consistent theory and classical theory predictions are indicated in figure 3. The differences are functions of the helical wrap angle and are greatest for a equal to 45°. At this angle, consistent theory predictions are about 80 percent of classical theory. For isotropic cylinders with the same radiusthickness ratio, length-radius ratio and boundary conditions, consistent theory predictions are also about 80 percent of classical theory (ref. 43). The results suggest that prebuckling deformations in

filamentary shells possessing high shear stiffness are an important consideration for accurate buckling predictions.

Imperfection sensitivity indices for the simply supported glass-epoxy cylinders are shown in figure 4. Calculations of the index b were made using the present theory (solid curve), as well as the theory of references 23 and 24 (dashed curve). The results for the sensitivity index b have been normalized by the index b_{iso} for an isotropic cylinder having the same R/t and A/R as the present cylinders. The values of b_{iso} obtained from the theory of references 23 and 24 agreed well with unpublished data (ref. 44) by J. W. Hutchinson. In plotting results on figure 4, computed data have been linked by straight line segments to indicate the points at which discrete calculations were made.

The results shown in figure 4 indicate similar trends in relative imperfection sensitivity predictions based on the two theories considered. The differences in magnitude of the imperfection sensitivity indices are attributed to differences in definition of the perturbation parameter ξ . In figure 4, the normalized sensitivity index $b/b_{1.50}$ takes on its smallest values for helical wrap angles from 30 to 60° . Thus, both theories suggest that glass-epoxy cylinders with these wrap angles are desirable configurations since they have a relatively low index. Because of the high index values for α equal to 75° , this configuration is presumed to be undesirable.

The results of a recent imperfection study by Khot (ref. 14) using a classical approach which ignores load-induced deformations prior to buckling but considers an initial imperfection of specified shape, should

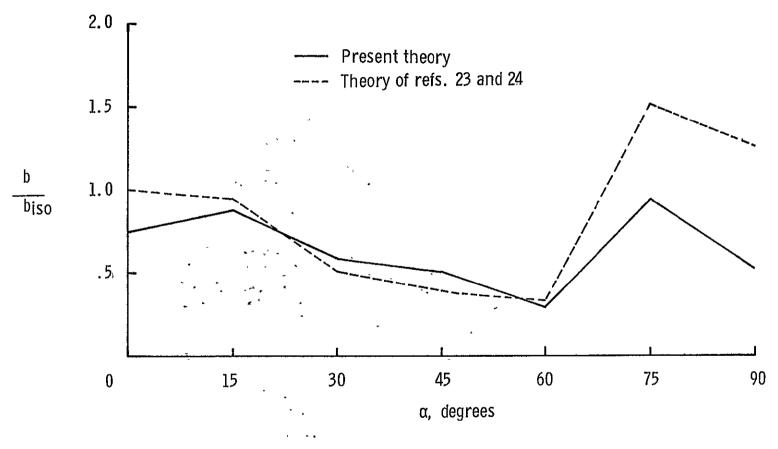

Figure 4. - Imperfection sensitivity indices for glass-epoxy cylinders.

also be noted. For three-layer glass-epoxy cylinders possessing 0, $-\alpha$, $+\alpha$, or 90, $-\alpha$, $+\alpha$, degree configurations, Khot found that maximum compressive buckling loads for small amplitude imperfections occur for shells where α is 45° . This result coupled with the present results suggests that the use of wrap angles near 45° in glass filament-wound cylinders may improve their buckling strength due to reduced sensitivity to initial imperfections.

Boron-Epoxy Cylinders

Buckling predictions for single layer, simply supported, boron-epoxy cylinders are presented in figure 5. In contrast to the glass-epoxy cylinders, consistent theory predictions for boron-epoxy cylinders indicate that axisymmetric collapse will occur for some wrap angles. As mentioned previously, the Koiter sensitivity index is undefined for these wrap angles. Note from figure 5 that consistent theory and classical theory predictions do not yield identical wrap angles for axisymmetric collapse. For consistent theory, collapse is predicted for wrap angles from 15 to 35° whereas for classical theory, collapse is predicted for gredicted from 30 to 60°.

As was the case in glass-epoxy cylinders, agreement between consistent and classical theory for boron-epoxy cylinders is a function of the helical wrap angle. Maximum differences between the two theories occur for wrap angles of 45 and 75°. For these wrap angles, consistent theory yields predictions which are roughly 85 percent of classical theory. Both classical and consistent theory buckling loads are

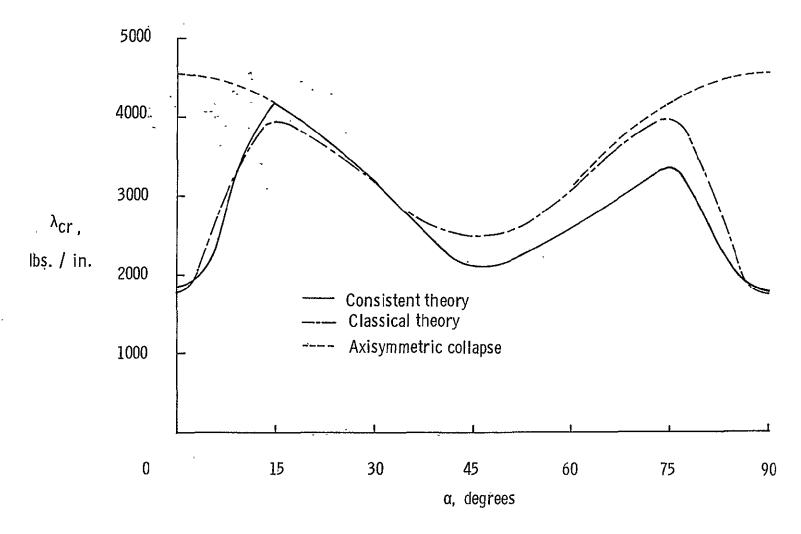

Figure 5.- Buckling loads for boron-epoxy cylinders (R/t = 100, A/R = 0.7, v_f = 0.50)

relatively high for cylinders with a wrap angle of 15° . The magnitude of load is believed to be a consequence of the high axial extensional and axial bending stiffness of boron filaments in this configuration, coupled with unusually large values of the product of Poisson's ratios $\mu_{\rm X}\mu_{\rm Y}$ (see table I). Since most of the structural stiffnesses of the shell are proportional to $1/(1-\mu_{\rm X}\mu_{\rm Y})$, large values of $\mu_{\rm X}\mu_{\rm Y}$ result in increased stiffness.

Imperfection sensitivity indices for boron-epoxy cylinders are presented in figure 6. Again, agreement in trend between the present theory and the theory in references 23 and 24 is good. Because of axisymmetric collapse, the sensitivity index is undefined for helical wrap angles where $15 \leq \alpha \leq 35$. Note from the figure that values of sensitivity indices adjacent to the zone of axisymmetric collapse may be quite different. For α equal to 10° , the sensitivity index (as well as the buckling load) is relatively high. On the other hand, for α equal to 40° , both the sensitivity index and the buckling load are low. These results demonstrate that cylinders which buckle near axisymmetric collapse loads are not necessarily desirable from the standpoint of reduced imperfection sensitivity.

A comparison of the magnitude of the sensitivity index for glass-epoxy cylinders (fig. 4) with boron-epoxy cylinders (fig. 6) in regions of minimum imperfection sensitivity reveals that boron-epoxy shells are less sensitive. Thus, shells with wrap angles around 45° would appear to be an attractive configuration in boron-epoxy cylinders. Khot's imperfection study (ref. 14) indicated that the 45° wraps in 0, $-\alpha$, $+\alpha$,

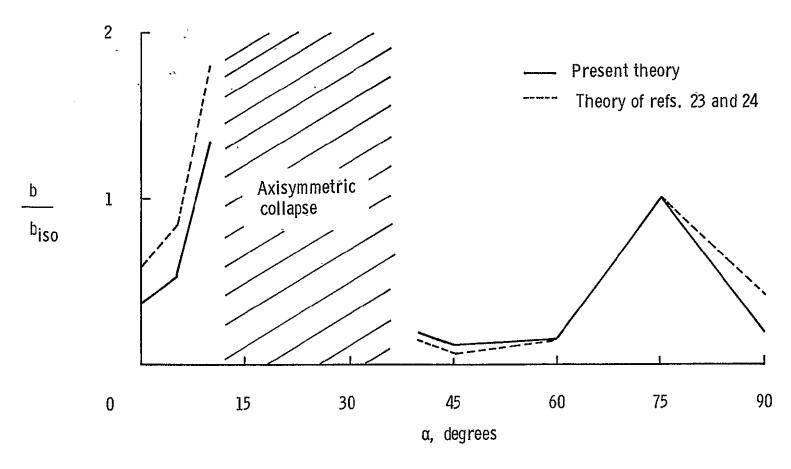

Figure 6.- Imperfection sensitivity indices for boron-epoxy cylinders.

and 90, -a, +a, configurations gave higher buckling loads for small amplitude imperfections. He also concluded that boron-epoxy cylinders were less sensitive to initial imperfections than glass-epoxy cylinders.

Boron-Aluminum Cylinders

In the studies of glass-epoxy and boron-epoxy cylinders, it was concluded that cylinders with wrap angles of 45° had reduced imperfection sensitivity. A shortcoming of this wrap angle in the simple configuration investigated ($\frac{1}{2}$ α) is its relatively low buckling load compared to other angles, especially in the case of boron-epoxy cylinders (see fig. 5). It seemed desirable to investigate more complex configurations, perhaps with other materials, which might possess both reduced imperfection sensitivity while still retaining relatively large buckling strengths.

An interesting concept in fiber-reinforced structures now being pursued by the NASA is that of employing a metal substrate and overlaying on it boron-epoxy tapes. This concept of selective reinforcement is attractive in that it reduces practical attachment problems and costs in using expensive filamentary material, yet at the same time provides good possibilities for structural weight savings. A recent study of tubular columns (ref. 45) in which metal tubes were overlayed with axially oriented boron filaments has produced some spectacular results for compressive buckling.

Because of current interest in the selective reinforcement concept, boron-aluminum cylinders were investigated. The cylinders were composed of two layers of equal thickness, one of aluminum, the other of boron-

epoxy with filaments at the Based on total thickness, the cylinders had the same radius-thickness ratios as the glass and boron cylinders already mentioned. The boron-epoxy layer was located on the outer surface of the aluminum. Preliminary calculations using classical buckling theory indicated that substantial differences in buckling load occurred depending on whether the boron layer was located on the inner or outer surface of the aluminum. The highest buckling loads were developed for the configuration chosen. This effect of layer sequence is the counterpart of the stiffener eccentricity effects discussed in references 9 and 38.

Buckling predictions for the boron-aluminum cylinders are presented in figure 7. Although classical theory predictions suggest axisymmetric collapse for $30 \le \alpha \le 45$, consistent theory predictions yield only asymmetric modes so that the imperfection sensitivity index exists everywhere. Note from figure 7 that substantial differences exist between consistent and classical theory predictions. The largest differences occur for α equal to zero where the consistent theory prediction is about 73 percent of the classical prediction. The maximum load carried by the boron-aluminum cylinders occurs for a wrap angle of 60° . The reason why cylinders with this wrap angle perform so well is not obvious, since the effects of prebuckling deformations and eccentricity in multilayered shells have not been thoroughly investigated. The only unique feature of the 60° wrap is its large value of $\mu_{\rm y}$ (see table I).

Imperfection sensitivity indices for boron-aluminum cylinders are presented in figure 8. Again, reasonable agreement in trends occur for

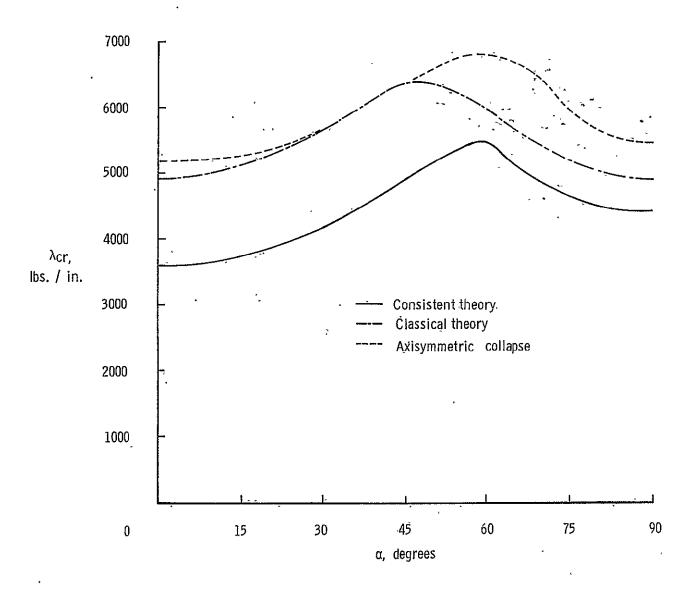

Figure 7.- Buckling loads for boron-aluminum cylinders (R/t = 100, A/R = 0.7, v_f = 0.50).

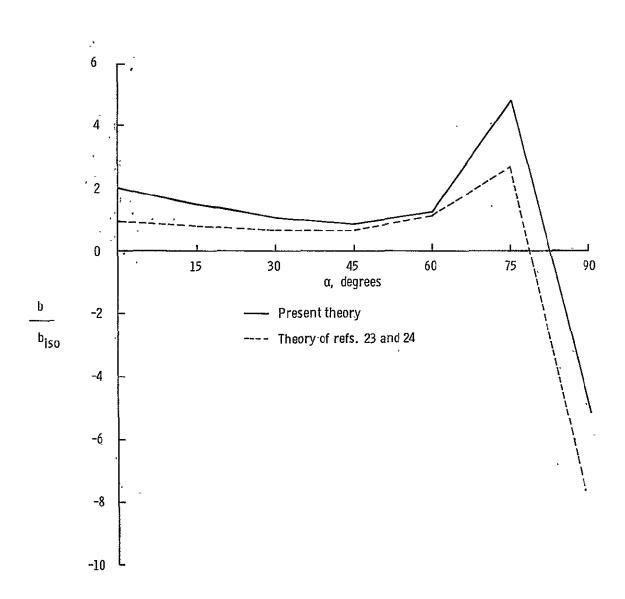

Figure 8.- Imperfection sensitivity indices for boron-aluminum cylinders.

the two versions of the Koiter theory. An interesting and encouraging result is the negative values of the normalized imperfection sensitivity index which occur for α equal to 90° . Negative values indicate a positive slope of the load-shortening curve for the cylinder in the post-buckling region. While this result is somewhat unexpected, it may be explained by observing that for α equal to 90° , the cylinder behaves as a ring-stiffened shell with very closely spaced, stiff (boron-epoxy) rings located on the outer aluminum surface. There is some evidence in the literature that ring-stiffened shells have unusual postbuckling behavior. In postbuckling studies, both Thielemann (ref. 10) and Shang (ref. 12) have found relatively large minimum postbuckling loads for ring-stiffened cylinders, thereby suggesting that they possess little imperfection sensitivity.

Relatively small imperfection sensitivity is also indicated for the 45° configuration. The magnitude of the normalized index, however, is much closer to unity than that for boron and glass cylinders with the same wrap angle. Thus imperfect boron-aluminum shells in this configuration would be expected to perform about the same as imperfect isotropic shells.

A somewhat frustrating law appears to evolve from the present investigation. As the compressive-load carrying capability of fiber-reinforced cylinders is improved by varying the filament orientation, the structure's sensitivity to imperfections becomes larger. An attractive fiber-reinforced cylinder configuration has been identified, however. Because of a positive slope in its postbuckling load-shortening

curve and its reasonably good load-carrying ability, the 90° or circumferentially wrapped boron-aluminum cylinder appears to be the most desirable of the configurations investigated herein. Whether its performance will be superior to configurations with greater potential load-carrying capability but greater imperfection sensitivity can only be determined by experiment.

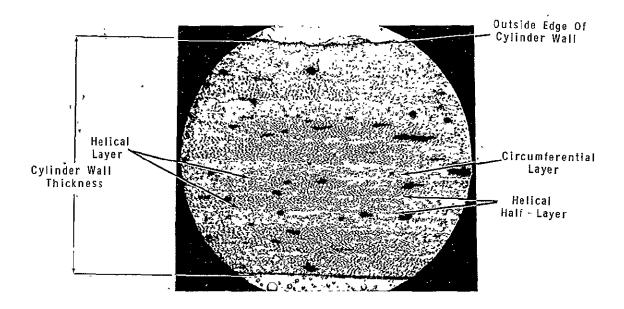

X. EXPERIMENTAL INVESTIGATION

Test Specimens

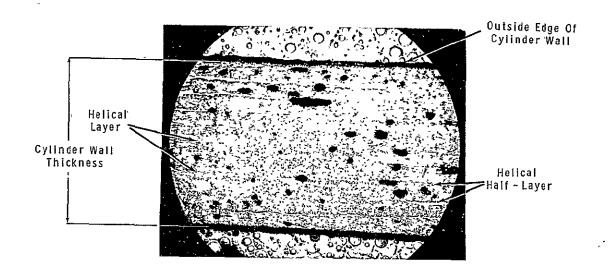

To investigate the buckling behavior of fiber-reinforced cylindrical shells, compression tests were conducted on 12 filament-wound, glass-epoxy cylinders. The test specimens had an inside diameter of 30 inches, were 30 inches long, and had a nominal thickness of 0.072 inch. The cylinders were wrapped in helical layers composed of two half layers, with filaments oriented at angles $+\alpha$ or $-\alpha$ measured from the cylinder axis. The variables in the test program were the helical wrap angle α and the cylinder wall configuration.

Six of the cylinders had walls composed entirely of five helically wrapped layers in the sequence $\pm \alpha$, $\pm \alpha$, $\pm \alpha$, $\pm \alpha$, $\pm \alpha$. The walls of the other six cylinders were composed of four helical layers and four circumferentially wrapped layers in the sequence $\pm \alpha$, 90, $\pm \alpha$, 90, $\pm \alpha$, 90, where the last circumferential wrap (+90) formed the external surface of the cylinder. Photomicrographs of the two cylinder wall configurations are shown in figure 9. For cylinders containing circumferential wraps, the helical layers at $\pm \alpha$ can be seen to be roughly twice the thickness of the circumferentially wrapped layers.

Table II contains material data for the cylinder constituents. The properties shown for glass fibers are typical of those usually employed for type E glass filament. Values of modulus and density shown for the ERL-2256 epoxy resin were obtained from compression tests of four 3-inch-diameter, solid resin cylinders about 6 inches long. The cylinders were cured with the same curing cycle as the test specimens, that is, 250° F for 2 hours. The solid cylinders were instrumented with both Tuckerman

(a) Cylinder 2

(b) Cylinder 12

Figure 9.- Photomicrographs of wall of test cylinders.

optical strain gages and differential transformer gages. The four cylinders were tested in compression at a loading rate of 20,000 pounds per minute. A typical stress-strain curve generated on an X-Y plotter by the transformer gages is reproduced in figure 10. All cylinders appeared to be capable of straining indefinitely at maximum load so that the tests were terminated when about 6 percent compressive strain had been experienced by the cylinder. No apparent damage could be observed at the conclusion of the test. Based on the test results, ERL-2256 appears to have a proportional limit of about 10 ksi in compression.

The dimensions and helical wrap angles of the glass-epoxy test specimens are presented in table III. The values of total wall thickness t shown are the average of several measurements taken at random locations. The scatter in individual measurements was ±4 percent of the value tabulated and is attributed to the irregular outer surface of the specimens. It should also be noted that the outer surface of each specimen was reinforced at each end with circumferentially wrapped layers about 1-1.3 inches wide with thickness equal to that of the shell. The purpose of this reinforcement was to prevent local crippling due to the end loads.

The fiber volume fraction v_f , the resin volume fraction v_r , and the void volume fraction v_v , expressed as percentages, are also presented in table III. The fiber volume fractions were determined by elevated temperature exposures of two or three coupons cut from the wall of each specimen. The coupons were subjected to a temperature of 1100° F for a period of 3 hours to permit virtually all of the resin in the

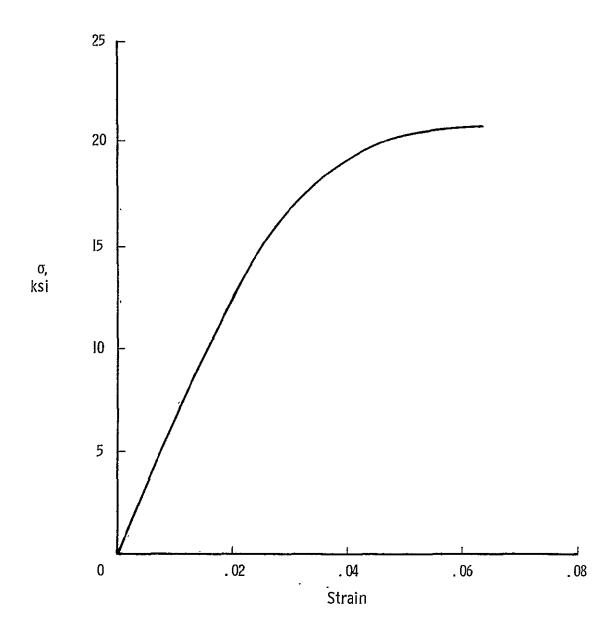

Figure 10.- Stress-strain curve for 3-inch-diameter ERL-2256 epoxy block loaded in compression.

coupon to decompose. The remaining glass was weighed and the equivalent fiber volume fraction was calculated using the values of density presented in table II. Prior to heating, the volume of each coupon was determined using Archimedes' principle. The resin and void contents were then calculated using the glass volume fraction together with the total volume and the density of resin quoted in table II. Although widely used, this method of determining void content is not extremely accurate, so that the true void content probably can be determined only to the nearest half a percent. It should be noted that the volume fractions of table III together with studies of photomicrographs of specimen walls suggest that the quality of the test specimens was only fair. Well-made glass-epoxy, filament-wound cylinders usually possess fiber volume fractions of about 65 percent while those of the present specimens are about 51 percent.

Test Procedure

Each of the 12 cylinders was instrumented with 16 wire-resistance strain gages with a gage length of 6 inches. The gages were bonded in back-to-back pairs on the surfaces of the cylinder and oriented in the axial and circumferential directions at the middle of the cylinder about 90° apart. The purpose of the axial gages was to measure initial strains from which the axial extensional modulus could be calculated, and to detect any bending deformations which might suggest buckling of the cylinder wall. The circumferential gages were present to measure strains from which Poisson's ratio $\overline{\mu}_{\rm X}$, associated with loading in the axial direction, could be determined. Additional instrumentation consisted of

two linear differential transformers which were used to track the relative motion of the testing machine platens.

For testing purposes, a 3/8-inch plywood bulkhead was inserted at each end of the cylinder to ensure that the ends of the specimen would remain circular. The cylinders were tested flat-ended in compression in the Langley Research Center's 1,200 kip-capacity testing machine. The loading head of the testing machine was carefully alined to promote uniform loading of the cylinders by checking strain distributions in the axial strain gages under small loads. The buckling test consisted of a single load cycle to failure at a loading rate of 5,000 pounds per minute. During the test, data were recorded at a virtually continuous rate on the Langley Central Digital Data Recording System.

Test Results

Elastic constants. The data obtained during the tests were reduced by computer and presented in the form of load-strain or load-displacement curves for each specimen. A sample plot of data for cylinder 10 is shown in figure 11. Data from the axial and circumferential gages have been plotted so that back-to-back pairs of gages have the same origin. For convenience, only the magnitudes of strain have been plotted. The average slope of the axial strain data was linear over a wide range of the loading history, and values of slopes determined from individual pairs of gages were in good agreement. The average of the linear slopes of the axial gages expressed as a Young's Modulus is presented in table III as \overline{E}_x . Values of \overline{E}_x deduced from the transformer measurements of overall

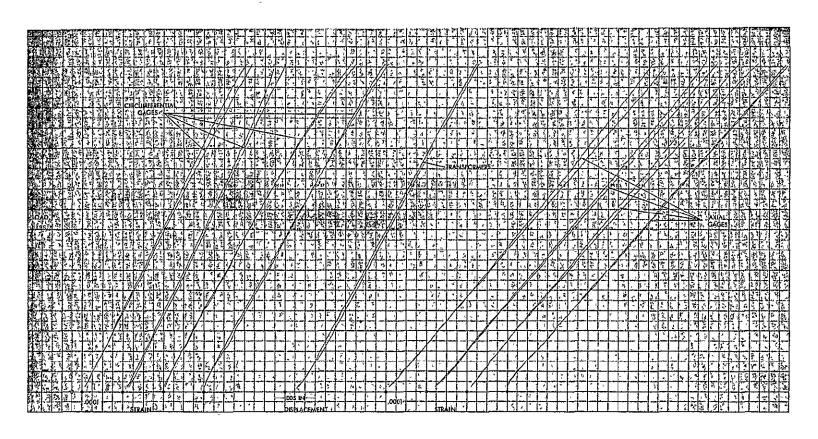

Figure 11. - Sample plot of cylinder test data.

shortening after corrections for the cylinder end reinforcement were in reasonable agreement with the axial strain-gage data.

Data from the circumferential gages were somewhat more nonlinear, and in some cases, substantial differences in individual gage slopes existed. The initial slopes of the circumferential gages were used to determine Poisson's ratio of each cylinder by dividing \overline{E}_X by the average of the circumferential slopes. The Poisson's ratio associated with circumferential strain induced by axial load $\overline{\mu}_X$ is also shown in table III. The underlined values in the table are values in which large variations in individual circumferential gage slopes were present.

The test data for elastic constants are compared in figures 12 to 15 with theoretical predictions for total extensional stiffness of the cylinder wall based on references 33 and 35. It can be seen that theory and experiment are in good agreement for the extensional modulus of the cylinder wall and in fair agreement for Poisson's ratios in spite of the scatter in data. The results suggest that the techniques employed herein for predicting elastic constants yield good engineering estimates of structural stiffnesses.

Buckling. Failure of most of the test specimens was accompanied by a loud report and the appearance of two tiers of large, diamond-shaped buckles uniformly distributed around the cylinder. As suggested in the load-strain curves of figure 11 which are plotted up to maximum load, no strain reversal was apparent prior to failure. The maximum load carried by the cylinder $\lambda_{\rm exp}$ is presented in table III. A photograph of a buckled cylinder is presented as figure 16. An observation associated

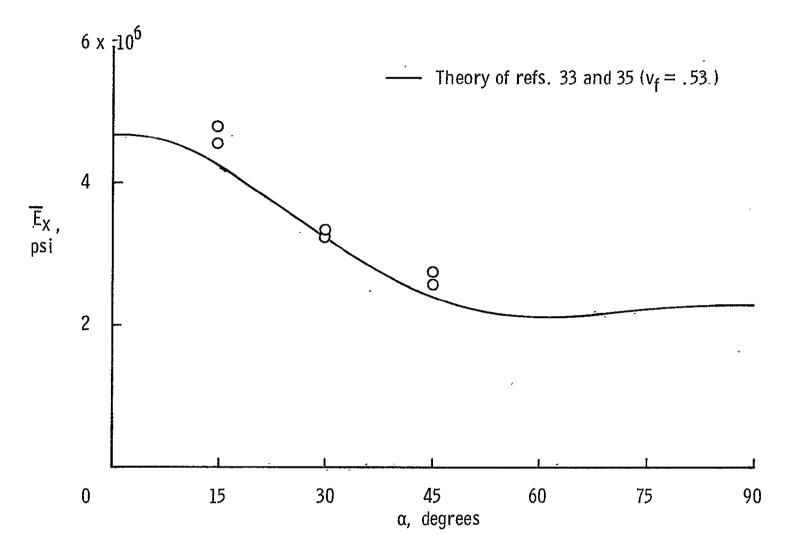

Figure 12.- Extensional moduli for test cylinders with alternating helical and circumferential wraps (cylinders 1 to 6).

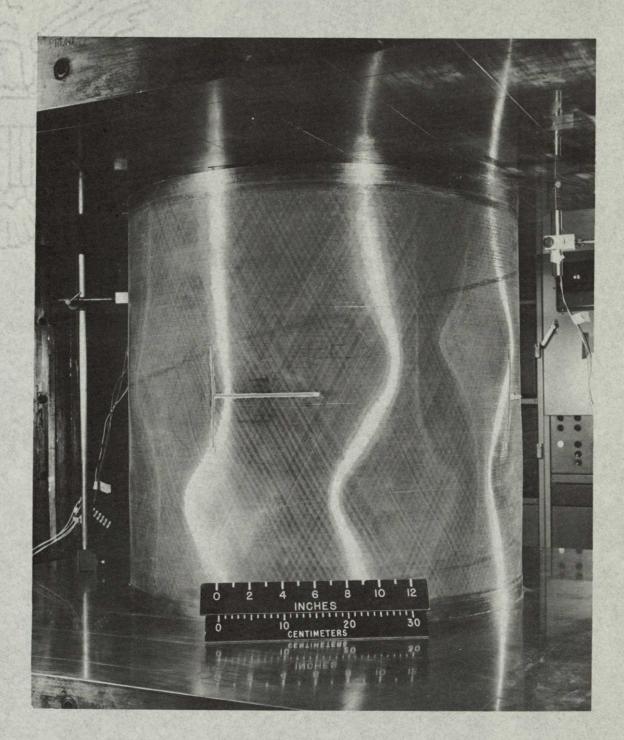

Figure 16. - Buckled test cylinder.

with the two specimens having 30° helical and circumferential wraps (cylinders 3 and 4) should be noted. On both these specimens, buckles appeared only on roughly one-half of the shell surface. As a matter of routine, before unloading, the specimens were prepared for photography by removing instrumentation wiring. In both cylinders, during this time period, a uniform buckle pattern suddenly developed, replacing the original, nonuniform pattern with no large changes in load or platen shortening. Since all specimens were tested with the same procedure, it appears that nonuniform buckle patterns might be an intrinsic characteristic of that wrap configuration. The particular configuration (±30, 90) happens to possess two-dimensional isotropy with regard to bending and extensional stiffness (but not complete isotropy due to lack of symmetry about the shell midsurface). It seems, experimentally, that less isotropic wrap configurations possess more uniform postbuckling patterns.

Comparison of Theory and Experiment

The experimentally obtained buckling loads for the test cylinders with alternating helical and circumferential wraps are compared with theoretical predictions in figure 17 and table III. The theoretical loads $\lambda_{\rm cr}$ were based on the simple support boundary conditions previously mentioned. The computations were performed using the consistent theory taking into account nonlinear prebuckling deformations (ref. 41). A few calculations using the clamped boundary conditions

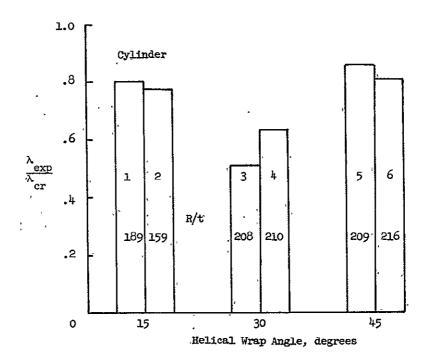

Figure 17.- Comparison of theoretical and experimental buckling loads for test cylinders with alternating helical and circumferential wraps.

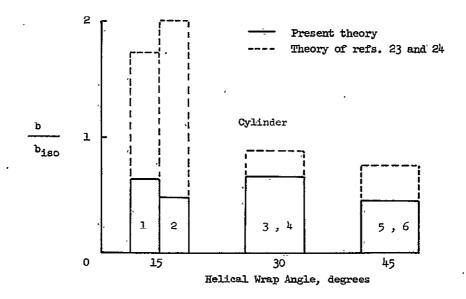

Figure 18. - Imperfection sensitivity indices for test cylinders with helical and circumferential wraps.

$$N_{X_{1}} = 0$$

$$v_{1} = 0$$

$$w_{1,x} = 0$$

suggested that differences between clamped and simple support calculations were small because of the length of the test specimens.

The trends shown in figure 17 indicate that the greatest difference between theory and experiment occurs for a wrap angle of 300 in cylinders 3 and 4. As mentioned previously, these cylinders possess two-dimensional isotropy with respect to bending and extensional stiffness, and behaved somewhat differently at buckling than the other, less isotropic cylinders in the test program. If the data in figure 17 for wrap angles of 30° and 45° are compared, it is evident that, for cylinders with nearly identical radius-thickness ratios, agreement between theory and experiment is much better for the less isotropic configuration (that is, 45°). Moreover, from table III it can be seen that analytically, the 30° configurations were expected to carry more load than the 45° configurations, whereas experimentally the reverse was true. Presumably, the reason for this unusual phenomenon is associated with the 45° configuration being less imperfection-sensitive than the nearly isotropic configuration. Thus, the present tests offer experimental evidence that certain filament orientations can enhance the buckling strength of a cylinder due to their decreased imperfection sensitivity. Direct comparisons between the 15° and 30° configurations are complicated due to the differences in radius-thickness ratios.

Imperfection sensitivity indices for cylinders 1 to 6 are presented in figure 18. The indices have been normalized by the index b_{iso} for isotropic cylinders of the same geometry. Results are shown for both the present theory and the theory of references 23 and 24. Agreement between the two theories is fair except for a wrap angle of 15°. The large value obtained for the sensitivity index at this angle from the referenced theory is not presently understood.

The trend of data from the present theory, however, is quite encouraging in that maximum values of the sensitivity index occur at 30°. Thus the Koiter theory predicts that cylinders 3 and 4 should be most imperfection sensitive. This result is in agreement with the experimental data, if it is hypothesized that the more sensitive buckling of a structure is to geometric imperfections, the lower is its value of $\lambda_{\rm exp}/\lambda_{\rm cr}$. It was expected that the sensitivity index for wrap angles of 30° would be about the same as an isotropic cylinder so that $b/b_{\rm iso}\approx 1$. The lower value of the normalized index shown in figure 18 is believed to be a consequence of the antisymmetry of the wall of the cylinder.

The experimentally obtained buckling loads for the test cylinders with helical wraps are compared with theoretical predictions for simply supported cylinders in figure 19 and table III. From figure 19, the only obvious trend in the data is the lack of reduction in values of $\lambda_{\rm exp}/\lambda_{\rm cr}$ as R/t is increased from 160 to 225. In isotropic cylinders, of course, some reduction would have been expected even in this relatively small change of R/t.

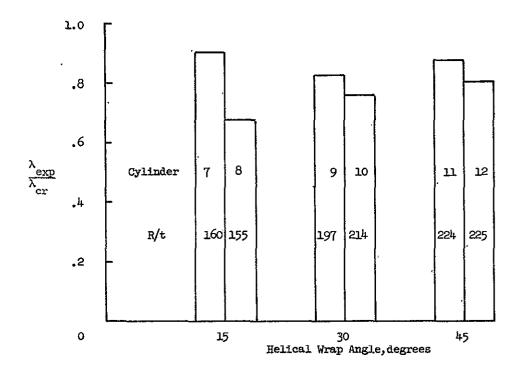

Figure 19. - Comparison of theoretical and experimental buckling loads for test cylinders with helical wraps.

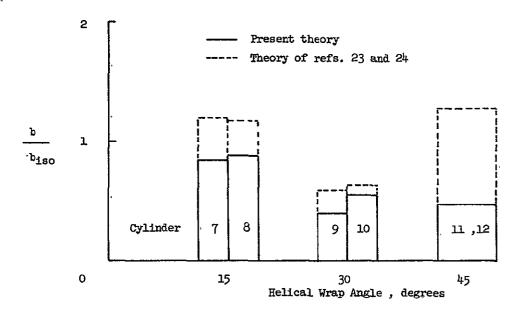

Figure 20. - Imperfection sensitivity indices for test cylinders with helical wraps.

For the 15° configuration, the data for cylinders 7 and 8 are inconsistent. From table III it can be seen that even though cylinder 7 was thinner than cylinder 8, it carried more load. Volume fractions and thicknesses were carefully reinvestigated, but no reasons were apparent to explain the discrepancies in the data.

Imperfection sensitivity indices for cylinders 7 to 12 are presented in figure 20. Agreement between the two theories presented is fair except for large disagreement for a helical wrap angle of 450. This anamoly was unexpected, since the agreement for this wrap angle for glass-epoxy cylinders with R/t = 100 was much better (see fig. 4). figure 20, variations in R/t make comparisons between wrap angles difficult. However, the trend of the indices for the present theory suggests that cylinders with wrap angles of 30° and 45° should perform better than isotropic cylinders of the same radius-thickness ratio. high values of $\lambda_{\rm exp}/\lambda_{\rm cr}$ shown in figure 19, especially for the largest R/t (cylinders 11 and 12), tend to support this prediction. sensitivity indices for cylinders with the lowest radius-thickness ratio suggest that their buckling behavior should be about the same as isotropic cylinders. The values of $\lambda_{\rm exp}/\lambda_{\rm cr}$ for cylinders 7 and 8, and the scatter in data seem to support this prediction also. Thus the trends in buckling data suggested by the sensivitity indices of the present theory are in fair agreement with experimental buckling data.

XI. CONCLUDING REMARKS

A theory has been developed to assess the sensitivity of buckling of axially compressed, fiber-reinforced cylindrical shells to small geometric imperfections in the shell wall. Following the work of Koiter (ref. 19), an index of imperfection sensitivity is obtained by investigating the character of the initial postbuckling region for a geometrically perfect cylindrical shell. The theory presented herein differs from existing applications of Koiter theory in that it is developed by using techniques of perturbation theory. The theory represents an extension to cylindrical shells of the plate postbuckling theory derived by Stein (ref. 25). Using Donnell-von Karman strain-displacement relations, the postbuckling equations are obtained for a multilayered, orthotropic cylinder in which the principal axes of orthotropy in each layer are alined with the longitudinal and circumferential coordinates of the shell. The imperfection sensitivity index is identified by suppressing secular terms in the perturbation and employing a suitable definition of the perturbation parameter. The governing equations were solved by finite difference techniques and by exploiting Gaussian elimination. A computer program to solve the large systems of simultaneous equations resulting was developed for the CDC 6600 series computer.

The results of an investigation of the imperfection sensitivity index for fiber-reinforced shells have been presented. Glass-epoxy, boron-epoxy, and boron-aluminum shells having various helical wrap angles were studied in order to identify wrapping configurations of minimum imperfection sensitivity. In conducting the investigation, both the

present theory and an extension of existing theory to multilayered, orthotropic shells were employed. Agreement between predicted sensitivity indices based on the two theories was reasonably good. Computed results for buckling in this investigation suggest that substantial differences (up to 27 percent) can exist between classical and consistent theory predictions for buckling, depending on the wrapping configuration. The differences are attributed to the neglect of load-induced prebuckling deformations in classical theory.

The studies of helically wrapped cylinders indicated that 45° was a desirable wrap angle in both glass-epoxy and boron-epoxy cylinders. For wraps with small imperfection sensitivity, boron-epoxy shells appeared to be more desirable than glass-epoxy shells. The most desirable shell configuration uncovered in the investigation was that of an aluminum shell overwrapped with a circumferentially wound boron-epoxy layer. This configuration was found to possess a positive postbuckling slope and appears to behave much like a ring-stiffened cylinder.

The results of an experimental program to investigate the buckling behavior of fiber-reinforced, glass-epoxy cylinders have been presented. Compressive buckling tests were conducted on twelve 30-inch-diameter filament-wound cylinders with various wrap angles. Elastic constants derived from data prior to buckling were compared with analytical predictions. The agreement between theory and experiment suggests that the approximations employed to estimate structural stiffnesses of the cylinder wall are valid. Cylinder buckling loads varied from 50 to 90 percent of consistent theory predictions, depending on wrap angle. Comparisons of calculated sensitivity indices with the cylinder buckling data show

both the theoretical and experimental results reported herein demonstrate that certain fiber orientations can enhance the buckling strength of geometrically similar cylinders. These configurations appear to possess reduced sensitivity to geometric imperfections present in the cylinder wall prior to loading. The present results suggest the desirability of further experimental investigations into the buckling behavior of configurations such as the circumferentially wrapped boron-aluminum cylinder.

XII. ACKNOWLEDGMENTS

The author wishes to express his thanks to the National Aeronautics and Space Administration for permitting him to use its facilities to perform this research. He also wishes to thank Drs. Manuel Stein and Paul A. Cooper of NASA for their council and encouragement, and Dr. Daniel Frederick, Professor of Engineering Mechanics, Virginia Polytechnic Institute, for his continuing efforts to provide his students with a sound education in the fundamentals of Engineering Mechanics. Finally, he wishes to thank his wife, Jo-Ann, for without her patience, consideration, and cooperation, this research might never have been accomplished.

GSJS torsional stiffness of stringer

. BS stringer spacing

Some conversions between the program notation and the notation of the paper which may not be self-evident are:

ŴOX

WOXX

WOXL

WOL

MØDRES modified residual resulting from taking determinant of left-hand side of buckling equations (see left-hand side of equation (62))

A listing of the program together with a sample case for the circumferentially overwrapped boron-aluminum cylinder follows.

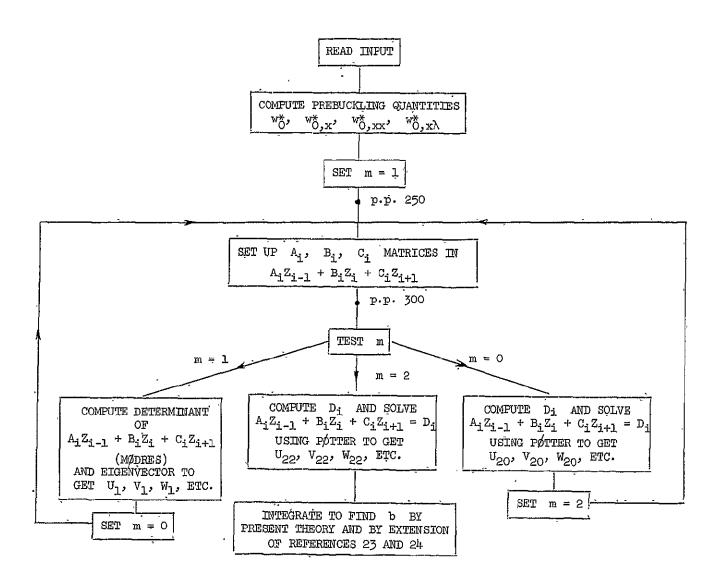

Figure 21.- Flow diagram for program SICK.
